Volunteers have been found most useful in this clinic. One is trained to take histories. A second volunteer who assists the nurse is given the responsibility of directing the children to the x-ray and electrocardiographic technician, of collecting and labeling urine specimens, and of weighing and measuring the children, and a third volunteer takes the doctor's notes. The certificating officer of the Department of Education is responsible for ascertaining whether or not the children are eligible in regard to age and grade for working certificates. She secures the children's school records and birth certificates for this purpose. She notifies the principal when the children are expected to return to the clinic and makes reports to the principal about the diagnoses of the children and whether they have been granted working certificates. The certificating officer also issues working certificates when they are recommended by the doctor.

COST OF EXAMINATION.—The expense of the Department of Health Diagnostic Cardiac Clinic has been estimated according to the initial and operating costs. The only omission has been the cost of the x-ray apparatus and of chairs and desks, all of which were purchased for the use of the tuberculosis clinics. For the purpose of this study, the cost of all equipment is estimated as nearly as possible according to prices quoted in 1930 which amounts to \$1,851.59. As the clinic was set up to examine 1,000 children a year, the operating cost has been estimated on this average,

making the expense of a complete physical examination, including the electrocardiogram, urinalysis, and x-ray, \$3.20 per child.

RECORDS AND FORMS USED.—The records used have been those of the Heart Committee of the New York Tuberculosis and Health Association. These are in three sections: history, physical, and progress record. In addition to these records, mimeographed forms of instructions to the child, parent and school nurse, as well as correspondence forms with the private physician are also used.

SUMMARY

The organization, procedures, and cost of maintenance of the diagnostic cardiac clinic of the Department of Health of New York City are described in detail in this report. This clinic was created to reduce to a minimum errors in the cardiac diagnoses of school children who apply for working papers. It was believed that the diagnosis of organic heart disease in a large percentage of the cases was incorrect and that therefore many children were unjustifiably deprived of employment. An analysis of the data accumulated in the last two years proves that assumption to have been correct. It shows that the diagnosis under the previous system was wrong in over 50 per cent of the cases.

The services of the clinic were extended beyond the original purpose. Many children with organic heart disease were not under medical supervision, and the clinic felt obligated to encourage such care for them. For this purpose the clinic has developed a consultation service between the nurse and parent. To help the doctor and also the child, the entire clinical data and recommendations are made available to the physician in charge of the child. The success of this plan of procedure is evidenced by the increasing cooperation of the physician with the clinic.

Another valuable service to the child is the work supervision and vocation guidance rendered by the Employment Center for the Handicapped. The information which the child receives about the types of employment and working conditions for which he is suited should be of value to him in choosing employment after the age of 17, when he is beyond the control of the clinic.

HEART DISEASE AMONG CHILDREN OF SCHOOL AGE

J. V. DE PORTE, Ph.D.

Director, Division of Vital Statistics, New York State Department of Health, Albany, N. Y.

The usual method of measuring the health of a people is by means of the death rate; and yet, from a broad point of view the prevalence of sickness is certainly of greater social significance. In order to add to the limited amount of information that is available about general morbidity, the New York State Department of Health conducted, in 1927, a survey in certain rural sections in which over one hundred physicians voluntarily reported each week the cases of the more important diseases in their practice. This survey was followed in 1928 by a more intensive study in one county—Essex.

Among the several interesting facts disclosed by both surveys, the importance of heart disease as a cause of sickness was brought out in a particularly emphatic manner. In the first survey, that of 1927, the physicians observed 4,123 cases of heart disease, a larger number than the total of reportable communicable diseases—3,212. In Essex County, 535 cases of heart disease were seen by the physicians in the course of the year 1928, and only 312 cases of the reportable group.

These findings led the Department, in 1931, to make a comprehensive investigation of the morbidity from heart disease in a general group of the population and among children of school age.

The purpose of the present paper is to summarize the results of the school survey which was made possible by the kind co-operation of the State Department of Education and the school physicians of twelve cities and large villages: Albany, Binghamton, Bronxville, Jamestown, Mount Vernon, Niagara Falls, Ossining, Oswego, Peekskill, Rome, Troy, and Utica.

By the end of the academic year 1930-1931 these school physicians reported 442 cases, diagnosed as a result of routine and, in some cases, of special examinations. The number of children examined was approximately eighty-six thousand; the incidence rate was, therefore, 5 per 1,000. The 1930 report of the White House Conference stated that "figures generally ac-

cepted, determined by intensive studies on large groups of children, chiefly in the school age, place 0.5 to 1.5 per cent of children among the five functional classifications of cardiac involvement generally recognized." Thus, our rate corresponds to the lowest in the range of figures found in other surveys. Applying this rate to the estimated population of the State between the ages of 5 and 20, we obtain 16,172 as the probable minimum number of cardiac cases among children of school age.

GENERAL RESULTS.—For purposes of discussion of the several types of heart disease among children, we have added to our group 192 cases under 20 years reported by the physicians who participated in the more comprehensive general survey of the morbidity from heart disease. The distribution of the 634 cases according to sex and age was as follows:

TABLE I.—CASES OF HEART DISEASE IN SCHOOL SURVEY OF 1930-1931 BY SEX AND AGE

Age	Total	Male	Female
Total	634	282	352
Under 5 years.....	14	9	5
5 to 9 years.....	160	71	89
10 to 14 years.....	255	107	148
15 to 19 years.....	197	93	104
Not stated	8	2	6

The largest number of cases was reported in the 10- to 14-year group, exceeding the number in the younger group, 5 to 9 years, by one-half among males and two-thirds among females.

ETIOLOGY.—In 74 cases the causative factor of the cardiac defect was not stated. In the remaining 560 cases, rheumatic infection was indicated in 302 instances (54 per cent): rheumatic fever, 175; tonsillitis, 109; and chorea, 18. Other acute infections were specified in 62 cases (11 per cent): pneumonia, 21; scarlet fever, 18; diphtheria, 12; influenza, 9; typhoid fever, 2. Cases of congenital heart disease numbered 40 (7 per cent). "Nervous heart," including a number of functional disorders, was given in 20 cases (4 per cent), thyrotoxicosis, 19 (3 per cent); carious teeth, 7 (1 per cent). In 81 cases

TABLE II—CASE OF HEART DISEASE IN SCHOOL SURVEY OF 1930-1931 ACCORDING TO ETIOLOGY BY AGE

Etiology	Total	Under 5 years	5 to 9 years	10 to 14 years	15 to 19 years	Not stated
Total	634	14	160	255	197	8
Congenital	40	7	7	14	11	1
Rheumatic infections	302	6	85	130	78	3
Rheumatic fever	175	4	41	77	51	2
Tonsillitis	109	2	38	49	19	1
Chorea	18		6	4	8	
"	62	1	13	23	24	1
"	20		8	6	6	
"	19		1	5	12	1
"	7		1	5	1	
"	15			1	14	
Other causes	14		5	6	3	
Unknown	81		17	28	34	2
Not stated	74		23	37	14	

(14 per cent) the etiology was said to be unknown

The weight of rheumatic infections was, in general, inversely related to age. In the youngest group, under 5 years, this factor was specified in 43 per cent of the cases, in the next age group, 5 to 9 years, rheumatic infection was indicated in 62 per cent of the cases, at 10 to 14 years, 60 per cent, while in the oldest group, 15 to 19, 43 per cent. Of the 15 cases of hypertension, 14 were in the 15 to-19 year group and only one in the preceding group, 10 to 14.

PATHOLOGY—In 542 cases (or 95 per cent of the cases in which reference to pathology was made), the type of cardiac damage was valvular disease—mainly mitral alone, 446 cases, combined with the aortic, 29, and with the tricuspid, 14. Damage to the myocardium was found in 24 cases (4 per cent). There were 3 cases of aortitis and 2 of pericarditis. In 63 cases no mention was made of cardiac damage.

Table IV shows the distribution of cases according to etiology and pathology.

OTHER FINDINGS—We shall next summarize briefly the remaining facts secured from the questionnaires.

In 312 cases, information was given regarding heart disease among other members of the family 78 "yes," 234 "no." In 105 cases no information was given regarding treatment. In the remaining 529 cases the questions relating to treatment were answered as follows:

	Total	Drugs	No drugs
Total	529	141	388
Rest prescribed	303	124	179
Restricted activities	150	32	118
Occasional rest in bed	90	54	36
Prolonged rest in bed	63	38	25
Rest not prescribed	226	17	209

More than one-fourth of the children (181) had their tonsils removed, abscessed teeth were extracted in 8 cases, and in one case thyroidectomy was performed.

TABLE III—CASES OF HEART DISEASE IN SCHOOL SURVEY OF 1930-1931 ACCORDING TO PATHOLOGY BY AGE

Pathology	Total	Under 5 years	5 to 9 years	10 to 14 years	15 to 19 years	Not stated
Total	634	14	160	255	197	8
Damage to valves	542	9	147	233	146	7

CONCLUSION

Health surveys in schools are of comparatively recent origin, but sufficient knowledge has already been accumulated to serve as a basis for constructive work. It has been estimated that practically 75 per cent of all cases of heart disease develop in children under 10 years of age. The implication of this statement is most important. The problem of our high mortality from heart disease should be attacked in the age period where most of the cases have their inception. Here the work of the school physician could be made of utmost importance, since it is

he who watches over the health of the children and has, therefore, an opportunity to discover the first symptoms, often long before the disease manifests itself sufficiently to attract the attention of parents.

A HELPFUL PLAN

An excellent method to provide a community supply of accessories needed in the medical care of the sick is reported in *Health News*, published by the New York State Department of Health at Albany. The plan is to establish a community loan closet, and it has been used with signal success by the village of Baldwinsville, Onondaga County. The project was developed by the local relief committee, a group of interested lay persons representing all classes in the community, which was organized by Mrs. George Campbell, chairman.

Nearly 200 men and women braved subzero weather to attend a community card party sponsored by the committee for the purpose of securing medical requisites for the poor. The price of admission was some article of use in the care of the sick. Donations including blankets, quilts, towels, sheets, and pillow cases, are said to have covered the platform of the village hall and to have taxed to capacity two six-foot wooden cabinets. In addition, sums of money were contributed.

These supplies are to be kept in the village

hall for use by the village nurse and local physicians in treatment of the indigent sick.

While this loan closet was developed for the care of indigent sick, supplies may well be lent to any family during illness, the equipment to be returned when there is no further need for it.

Without waiting for any elaborate red tape or staff of investigators, the St. Louis County Medical Society has hit on a simple plan to reduce charity grafting. Every applicant for free service is asked to make an affidavit as to his financial condition. "Do you own real property?" he is asked. "Are you, or any of your family, employed?" "What wage or salary?" "Have you a bank account?" "State your income." "How many dependents?" The paper can be filled out in ten minutes, and the applicant is required to sign it and take his oath before a notary that it is correct. And what is the result of this plan? Charity abuse at the County Hospital has dropped 60 per cent.

THE FAILING HEART OF MIDDLE LIFE

HAROLD E B PARDEE, MD

Associate Attending Physician, New York Hospital

It will be well to point out at the beginning what is to be understood by the term "failing heart." It is not meant to be confined exclusively to the shortness of breath on exertion which leads in the later stages to edema and general anasarca but is to include any sign that the heart may give to indicate that its function is disturbed. This will comprise various sensations over the heart such as pain, pressure, or palpitation, spontaneous attacks of dyspnea, and also certain spells of dizziness. Furthermore it may be considered foolish to labor the question of what is middle life, but after giving much attention to it, the answer does not seem to be so easy. For the purpose of this discussion the years from thirty-five to sixty have been used, admitting that at thirty-five many are still young and at sixty some are not yet old.

During this stretch of years we will find patients with signs of failing heart who are suffering from various etiologic types of heart disease (Table I). In the earlier years of middle age there are many with rheumatic valvular disease. Some of these have carried the condition since childhood, most of them since before twenty years of age. These patients continue to appear in considerable numbers until the age of fifty, but after this they are relatively few, most of them having died. After forty years

them in number. By the age of sixty, practically all of the syphilitic cases have died.

It is rare to find arteriosclerotic forms of heart disease before the age of forty, though it is not a great rarity. Every physician has probably seen at least one such case. After forty the frequency of this condition increases, and after fifty it is so great that these patients comprise well over half of all cardiac patients between the ages of fifty and fifty-nine.

Another small group should be mentioned. Those with cardiac disease associated with hyperthyroidism. This is often found before the time of middle life. It is most frequent in those between thirty-five and forty five, but it is found with diminished frequency until the late fifties.

In summary, then, from thirty-five to forty years of age there will be almost entirely rheumatic cases with a few due to hyperthyroidism and a few to syphilis. From forty to fifty, half of the patients will be rheumatic, the other half chiefly syphilitic and arteriosclerotic in about equal numbers, with a small number of hyperthyroids. From fifty to fifty-nine the patients will be more than half arteriosclerotic, with the other half made up chiefly of syphilitic and rheumatic cases in about equal numbers, with a very few suffering from thyroid disease.

Having thus briefly sketched a picture of the etiological types of heart disease which will appear in patients during middle life, we shall now discuss the symptomatic manifestations of the failing heart in these groups. It is better to consider them in this way by etiologic groups because there are certain special differences in the clinical pictures presented by the patients in each group when they develop symptoms of failing heart.

The youngest patients, those with old rheumatic valvular disease will have probably known of the presence of this condition for many years but will have been little troubled by its presence. Some few may not even have known that they had heart disease. Some will have been troubled

TABLE I—APPROXIMATE FREQUENCY OF CHIEF ETIOLOGIC VARIETIES OF HEART DISEASE PER 1,000 CASES SEEN DURING MIDDLE LIFE*

Age	Total	Rheumatic	Thyroid	Syphilitic	Arteriosclerotic
35-40	185	151	15	17	2
40-49	390	201	20	87	82
50-59	425	75	5	87	258
Total	1 000	427	40	191	342

* These figures are not the result of a special investigation but represent a combination of figures obtained from several sources.

of age a few patients with syphilitic aortitis and valvular disease are found. They are many fewer than the rheumatic cases at this age, only a little more than one third as many. After fifty, however, the rheumatic cases are fewer so that syphilitic cases in the older patients slightly exceed

by increasing shortness of breath, and some will have developed auricular fibrillation accompanied by shortness of breath on moderate exertion. These patients who have already developed symptoms, merely carry on into middle life the disturbances which they have begun before and do not properly belong in this discussion. Their disease may progress and the symptoms become worse, but this has little to do with the age of the patient; more with the activity of the rheumatic disease or the advanced degree of the valve lesion.

We are especially concerned with those who enter into middle life with valvular disease but without symptoms of cardiac dysfunction, perhaps even without knowledge of its presence. It has been estimated that there are 60,000 adults in New York City who are carrying about an unsuspected rheumatic cardiac disease. Some of these will develop symptoms as a result of an acute or subacute recurrence of rheumatic activity. A majority, however, will carry the damaged valves through the fourth decade and many through the fifth. Some of these patients develop symptoms of failing heart because of a low-grade sub-symptomatic rheumatic activity in the heart valves producing a marked degree of stenosis. Most of them do not do so until coronary arteriosclerosis complicates the picture. The symptoms of these patients are in no way different from those of other patients with arteriosclerotic coronaries, except that the heart tends much more frequently to develop insufficiency with congestive symptoms than in pure arteriosclerosis where the handicap of valvular disease is not present. Cardiac insufficiency in these patients develops slowly and slowly increases in severity. It is probably for this reason that so few of them survive the fiftieth year.

Syphilitic heart disease develops most insidiously, and unless the patient is subjected to physical examination from time to time, there will be a period of from ten to twenty years following the infection during which he will not know of the developing cardiac condition. He may have occasional attacks of palpitation due to premature beats or to paroxysmal tachycardia which last for a few minutes or intermittently for a few days or weeks. For the most part the syphilitic disease is silent until it has progressed from an aortitis to the development of aneurysm or

of a free aortic insufficiency due to a destructive lesion of the valves. These conditions usually produce symptoms between the years of forty-five and fifty-five, though occasionally earlier and sometimes later.

The symptoms of aneurysm are so varied in its earlier stages that it is not possible to go into detail here, but it will suffice to emphasize that it is a thing to be thought of when a man of middle age complains of dyspnea, cough, hoarseness, or difficulty in swallowing, for which no cause can be found in the heart or lungs. To establish the diagnosis by x-ray should not be difficult if only we will think of the possibility.

Syphilitic valvular disease has two chief manifestations: Shortness of breath and pain. The dyspnea may come on gradually over a period of from four to six months, and by this time, if not sooner, it will have reached a degree which will prevent most ordinary activity. The strikingly rapid progression of the dyspnea in these cases is in marked contrast to the usual course of rheumatic aortic insufficiency. The pain with syphilitic aortic insufficiency is mostly a result of the involvement of the mouths of the coronary arteries in the aortitis. Their mouths may become more or less closed off and the myocardium as a result suffers from ischemia and degeneration. The pain is somewhat like that of coronary arteriosclerosis, but it is less often the immediate result of effort than a spontaneous paroxysm. These paroxysms are not apt to be as prostrating and prolonged as is usual for those due to coronary thrombosis but still may be quite severe. One may be inclined to feel that a thrombosis has occurred during some of these attacks, especially if they lead to prompt death, but the pathological examinations do not demonstrate this to have occurred.

These patients at their age may, of course, have a complicating coronary arteriosclerosis, and if this is present, a thrombosis may really occur. The coronaries of most syphilitic hearts are relatively free from arteriosclerotic disease, but with aortic valve involvement it is common for the aortitis to involve their aortic orifices. This coronary occlusion and the resulting muscle degeneration afford the most probable explanation for the rapid progress of cardiac insufficiency in these patients once it sets in.

Patients who develop heart disease from hyperthyroidism do so almost exclusively by one mechanism, that is, through the development of auricular fibrillation. We must distinguish between the cardiac symptoms associated with hyperthyroidism and the more definite disturbances which can be designated by the term "disease." Tachycardia and palpitation in these patients do not constitute evidences of heart abnormality. The increased metabolism together with the increased receptivity of the sensorium serve to explain these symptoms. Arythmia of the extrasystolic type may occur, however, and also paroxysmal tachycardia, usually of auricular or nodal origin. These are not serious or important cardiac disturbances unless the tachycardia persists or appears overfrequently, for only under such circumstances does arythmia seriously interfere with the cardiac reserve. Auricular fibrillation, too, can occur in a paroxysmal form in these patients, but for a similar reason it is only when attacks are frequent or when it becomes permanent that it assumes much importance.

These arhythmias are due to the toxic effects of hyperthyroidism upon the heart muscle or upon the cardiac nervous mechanism. In patients under forty years of age they usually indicate a severe grade of thyroid disturbance, but in older patients they may occur with lesser grades of toxemia, probably because the older myocardium is more susceptible. Permanent auricular fibrillation is a matter of great importance, especially if it goes untreated for a time, for it leads to a severe cardiac insufficiency with visceral congestion and edema and eventually to cardiac enlargement with interstitial fibrosis. With treatment the heart can usually be kept slowed and the cardiac reserve improved, but the enlargement and the fibrosis remain and constitute the basic pathology of the hyperthyroid heart. As coronary arteriosclerosis comes on this adds to the difficulty in maintaining adequate cardiac reserve and the majority of these patients die of cardiac insufficiency before fifty-five years of age.

Though rare instances of coronary arteriosclerosis occur before forty years of age, it is not to be expected until at least forty-five years and not really expected until ten years later than this. About 15

per cent of all cases occur between forty and fifty and 44 per cent during the next decade, so that by sixty years, the end of middle life, we have collected 60 per cent of all cases.

The initial manifestations of arteriosclerotic heart disease are varied and depend somewhat upon the age at which they begin. In the younger age groups the first symptoms are usually anginal, either the angina of effort, first showing itself as pain or precordial discomfort on walking. More rarely the severe spontaneous attacks due to coronary thrombosis may be the first manifestation. Another though less common type of onset is with arythmia, either premature beats or auricular fibrillation. Arythmia will often accompany or follow anginal symptoms when the disease starts in this way. Cardiac insufficiency with dyspnea on effort and with or without edema is a rarer mode of onset in patients under fifty years of age, though it may follow coronary thrombosis. Cardiac insufficiency is more common in older patients, probably because it demands a more extensive myocardial lesion than develops at an earlier age. Coronary thrombosis in younger individuals is more likely to be followed by a good recovery than in those who are older. It is not uncommon to find a practically complete recovery, though there will often be a residue of the angina of effort or more rarely of cardiac insufficiency.

Patients under fifty years of age who start with the angina of effort may improve greatly and even recover entirely. It is more common, however, for them to have a certain amount of residual symptoms. After a time they are likely to develop coronary thrombosis, no matter whether their anginal symptoms have persisted or have been entirely recovered from. It is not definitely known whether those patients who have entirely recovered are any less liable to have thrombotic attacks than those who have continued to have a certain amount of pain on effort. I am certain that neither the amount of pain nor its ease of production can be taken as an indication of the severity of the lesion or of the liability to thrombosis.

Patients after fifty years of age often develop as the first sign of failing heart due to arteriosclerotic coronary disease, the syndrome of cardiac insufficiency with shortness of breath or fatigue. They may

also, as with younger patients, first show the angina of effort or an attack of coronary thrombosis or perhaps arrhythmia. The Adams Stokes' syndrome due to heart block, with dizzy or faint spells and possibly convulsions, is occasionally the mode of onset, but this is a relatively rare condition. Paroxysmal dyspnea occurring especially at night is another rare mode of onset in the older middle aged patients and has been called cardiac asthma. The underlying pathology of this last condition is undoubtedly coronary arteriosclerosis, but it is not clear what may be the reason that it sometimes has this peculiar manifestation. Coronary thrombosis at this age is more liable to be fatal and is less commonly followed by complete recovery. It is more liable to leave symptoms of cardiac insufficiency or the angina of effort.

The contribution of hypertension to the failing heart of middle life is a real one, though it is much more important as a contributing factor in the symptomatology of arteriosclerotic heart disease than as an isolated feature. Hypertension will give rise to cardiac enlargement but symptoms will not arise from the heart unless enlargement reaches an extreme degree which is uncommon, or unless arteriosclerotic coronaries make impossible proper nourishment of the hypertrophied muscle. Cases with hypertension usually develop symptoms after fifty years of age, and the symptoms are typical of coronary arteriosclerosis. Cases with uncomplicated hypertensive cardiac enlargement are sometimes subject to premature beats and paroxysmal tachycardia and auricular fibrillation. They may rarely develop slight symptoms of cardiac insufficiency. As long as coronary disease holds off, these patients do not usually suffer from cardiac symptoms. It must be emphasized that in these patients the arteriosclerosis affects predominantly the arterioles and smaller arterial branches rather than the main and larger divisions, so that thrombosis is less frequent than without hypertension.

This practically completes the picture of the failing heart in middle life. It will be seen that it involves several different etiologic varieties of heart disease. It is a gradual process which does not progress rapidly after its first appearance, except in the case of syphilitic valvular disease with failure, or as a result of coronary thrombosis. The outlook, then, should not

be pessimistic for the patient will probably survive by many years the date of his first symptoms. There is, of course, in arteriosclerotic cases the danger of a fatal attack of coronary thrombosis. This danger must be recognized, but it should be faced with equanimity by both the doctor and patient, for it may be postponed for many years. One should remember that a first attack will probably be survived, for only 20 per cent of cases die in their first attack. Even after one attack has occurred, the second may still be postponed for years, and 70 per cent of second attacks are survived.

To conclude, a word about treatment should be said. The use of digitalis in the patients with symptoms of cardiac insufficiency is in no way affected by the etiology or by the type of valvular or myocardial involvement. There may be cases that do not improve under treatment, but this does not necessarily indicate that digitalis is inactive—merely that its activity is unequal to the task in this particular case. Its action may be just short of the necessary degree and some additional procedure, such as tapping the chest or abdomen or using a diuretic to remove edema, may enable its benefit to become manifest.

It seems that there is more than ordinary danger involved in giving a toxic dose of digitalis to a patient who is suffering from cardiac failure after a coronary thrombosis. These patients are usually hanging so near the edge of life, when their lungs fill up with râles or their liver or peripheral veins become swollen because of increased venous pressure, that the circulatory disturbance due to a tachycardia or to the very frequent premature beats which may result from over-digitalization may be sufficient to turn the balance against them. It is not necessary to avoid digitalis in these patients, for it often seems to be beneficial in relieving pulmonary congestion; but it is most important to avoid a toxic dose, and this means not more than 10 cat units of digitalis in the first twenty-four hours for a patient of 150 lb. and after this not more than one every eight hours. At this rate of administration toxic effects will not often appear suddenly. Toxic rhythms seem especially liable to arise in patients who are receiving digitalis along with one of the purin derivatives, caffeine, theobromine, or theophyllin.

Digitalis is often of demonstrable value in ambulatory patients who are complaining of moderate dyspnea. It probably helps by its "tonic" or strengthening effect upon the muscle contraction. It is obligatory in patients with auricular fibrillation or flutter accompanied by rapid heart beat, no matter whether unusual dyspnea is present or not, for these patients benefit by having the heart rate slowed and maintained so. It may be useful for its strengthening of the muscle contraction in patients with complete heart block complaining of dyspnea, but when incomplete heart block is present, it may produce Adams Stokes' attacks which may offset the improvement of the cardiac insufficiency.

In coronary arteriosclerotic patients, or in others who are suffering from the effects of deficient blood flow, drugs of the purin group may be expected to be helpful. Theophyllin is the most active, theobromine is next, and caffeine a poor third in this field. These drugs dilate the coronary vessels so as to increase the blood coming through the more healthy collateral anastomoses, into muscle areas which are being poorly nourished by their own narrowed arteriosclerotic branches. The greater the number of healthy branches that remain, the more likely it is that these drugs will give benefit: The more diffuse the disease, the less chance that they will help. Perhaps it is for this reason that they are more useful in patients with the angina of effort than in those with cardiac insufficiency, for these latter usually have more extensive coronary changes.

Owing to its relative freedom from gastric irritation, theophyllin ethylenediamine is the most satisfactory preparation to give, and the dose may be 3 gr. three times daily at first, later reducing to $1\frac{1}{2}$ gr. four times daily, and still later to $1\frac{1}{2}$ gr. three times daily. This drug should be used for at least a month, and then it may be stopped for a time to be resumed if symptoms promptly increase. It is the author's belief that it is helpful when given for two or three weeks of each month as long as symptoms persist. It may even be of value in coronary thrombosis and should be given in 3-gr. doses by mouth or intravenously every four hours.

Finally a word about rest and exercise. Rest should be graded to the degree of

cardiac insufficiency. A patient who becomes dyspneic on walking two or three blocks is probably better off not to exert himself to this degree more than once or twice daily. I see no advantage to such a patient from avoiding lesser grades of activity. He is better to be up and about the house, even if this involves climbing one flight of stairs a day, than he will be when confined to bed. We are not dealing with an acute condition in these patients, and absolute rest is seldom indicated; at least, in the author's opinion, never for long periods of time.

Patients with the angina of effort also afford a problem as to the amount of rest to prescribe and the amount or activity to allow. If the condition has come on in the course of a few days or is increasing rapidly in severity, we should fear the approach of a thrombotic attack. This would call for the avoidance of any mental and physical strain and would indicate restriction to the house until the danger seems past. If the condition has come some weeks or months previously and is not increasing in severity, there does not seem much reason for avoiding any activity, including business, unless these activities demand periods of physical or mental strain. Walking, if short of the amount which produces pain, and business activity which is not fraught with tense or emotional moments do not seem harmful.

Patients who have had thrombotic attacks must remain in bed as long as fever persists and for at least three weeks more if the attack produced little prostration. After more prostrating attacks a proper minimum would be four or five weeks after the fever has gone. When the patient is allowed up he should be managed as one would treat a pneumonia convalescent, taking at least two weeks from bed to walking about on the floor, another one or two weeks before going out. At this time we must individualize patients depending upon the degree of their recovery and the presence of residual cardiac symptoms and signs. The electrocardiogram, as it returns to a more normal form after an attack, is sometimes a useful guide at this time to the process of healing in the myocardium.

ABDOMINAL PAIN IN CHILDREN

EDWARD SHERRARD RIMER, M.D.

New York, N. Y.

Pain in the abdomen is a common complaint among older children. It is so frequent that we may neglect its importance and fail to heed a danger signal. Pain may run the gamut as a symptom in a great variety of conditions. All the way from a bubble which gives the baby colic, to the sharp pain of an inflamed appendix, the symptom of pain in the abdomen demands our attention.

The seriousness of this symptom varies, not always in proportion to its severity. Interpretation of its significance in children is difficult. Their description of the character and location of the pain is vague, or they forget the details when the pain is gone. The memory of it fades rapidly—so the past history is not always helpful. Nausea may mean pain to a child. Different types of children react very differently to pain stimuli, so that one must constantly be on guard against exaggeration or even romancing. The nervous child may be very sensitive to pain, but the phlegmatic child also may give us a wrong impression by too little evidence of suffering.

Are we dealing with a functional disturbance, or has the child a disease of some intra-abdominal organ? To answer these questions we frequently need every help at our command.

No child with the symptom of abdominal pain should be dismissed from mind without an attempt to explain why he has pain. Frequently the explanation is not easy. Too often the diagnostic position is taken that pain in the abdomen means either that the child has appendicitis, or else he has eaten injudiciously. The author wishes to emphasize the diversity of disease in which abdominal pain must be considered.

At least 65 per cent of all illness in children is of the respiratory tract, usually of the upper air passages.

Brenneman pointed out, and his conclusions can easily be verified, that such affections are frequently accompanied or followed by abdominal pain. This pain may occur at the onset of the infection and be so severe that attention is directed to the abdominal condition and surgical in-

tervention may be considered; or the pain appears some time after acute nasopharyngitis or tonsillitis, and again appendicitis acute or chronic is suggested.

The character of pain in upper respiratory disease is dull, spasmodic, referred to the region of the navel, and is not accompanied by hyperalgesia of the skin. Muscular rigidity is absent. There is, however, deep tenderness in many cases. This latter sign is probably explained by enlarged and inflamed glands—mesenteric or retroperitoneal.

Prolonged history of abdominal pain is often elicited in these children.

The question of appendicitis arises not only in the mind of the physician but also in the mind of the parents. If operation is performed, a normal appendix and enlarged glands are found. The syndrome of frequent respiratory infections and abdominal pain should make one hesitate to advise operation.

CASE 1. P. F., age 10, who was taken ill December 9, 1932, with stuffy nose, temperature of 99° F., had acute nasopharyngitis. He complained of dull pain in the abdomen. The pain was not associated with digestive disturbances or constipation. No tenderness or other untoward sign was noted, but what seemed to be glands were palpable in both lower quadrants. The pain disappeared after two days. Such pain frequently occurs in respiratory infections.

CASE 2. H. M., age 8, was admitted to Bellevue Hospital on November 20, 1932, with vomiting and abdominal pain which had begun suddenly at 2 A.M. on the day of admission. She looked ill, the abdomen was distended, but there was no definite area of tenderness. Rigidity was doubtful. She had an acute tonsillitis and x-ray showed probable sinusitis. Operation for appendicitis was considered but deferred until morning, when the abdominal symptoms had disappeared. In spite of the acute infection, she had no elevation of temperature above 100° F. and yet the leukocyte count was 18,200 to 23,300; polys. 73 to 87 per cent. Next day the leukocyte count was 10,400; polys. 65 per cent. Her convalescence was uneventful.

A review of over 100 cases of lobar pneumonia in older children in the children's medical service at Bellevue Hospital during the year 1931, failed to reveal a case in which abdominal pain was so prominent as to make the consideration of an acute surgical disease of the abdomen

a feature in the diagnosis In 1932, however, there were 2 cases in which the diagnosis was in doubt

CASE 3 J H, age 6, was admitted to Bellevue Hospital on August 22, 1932, for vomiting and pain in the abdomen The temperature was 103° F There was marked tenderness in R L Q and rectal tenderness The leukocyte count was 21,000, polys 88 per cent A tentative diagnosis of ruptured appendix was made, but x ray showed pneumonia The temperature came down to normal in 2 days and the abdominal signs disappeared

Hospitalization with fluoroscopic and x-ray examination, with frequent leukocyte counts and urinalyses is an advantage, of course, yet even with constant observation, early in the disease, the diagnosis may be very difficult The higher and sustained temperature in pneumonia, higher leukocyte count, the grunting respiration, the cough and other respiratory symptoms, point toward pneumonia The more obstinate constipation, vomiting, the sharp localized pain, deep tenderness, and muscular rigidity speak for acute appendicitis

It must be remembered that fluoroscopic and x-ray examinations often do not confirm our suspicions of pneumonia during the early days

CASE 4 C S, age 9, was first seen on January 15, 1930 He complained of pain in R L Q past year at times—no relation to eating, bowels regular—was slightly tender opposite umbilicus on right side There was generalized swelling of superficial lymph nodes Hodgkins disease was ruled out [It should be remembered that in Hodgkins disease the superficial glands are enlarged but not matted or caseated, as in tuberculosis The retroperitoneal and mediastinal glands are affected with greater severity than the superficial nodes] Finally it was thought advisable to remove the appendix There were found enlarged retroperitoneal glands near the appendix which was long, but otherwise normal This boy was very prone to colds, otitis and sinusitis and was rarely free from enlarged superficial glands

Surgeons, the author believes, are agreed that many children present just such a picture as this last boy, where the operation for supposed chronic appendicitis reveals no pathological condition except enlarged glands in that region

These four children illustrate the syndrome of acute respiratory infections with striking abdominal symptoms

Pneumococcus peritonitis occurs without respiratory tract infection The infection may invade the peritoneum directly through the vagina in young girls

In a second group, we find definite pathological involvement of abdominal organs Pain is again a symptom, but not always conclusive in making the diagnosis This may be due to the child's inability to express his suffering in words Respiratory symptoms may mask the picture

CASE 5 D H, age 2 admitted to Bellevue Hospital October 17 1932 This boy had been ill two days with vomiting was constipated, and an enema was given but was not effectual The child was content to lie quietly in bed His breathing then became rapid and his fever rose Hospitalization was advised by his physician On admission he looked very sick His face was drawn and anxious as though he were in pain, although he did not complain Grunting expiration was noted He had a congested throat The abdomen was distended, tympanitic, and generally tender His temperature was 105° F respiration 60, and pulse 160 The leukocyte count was 7000 with polys 65 per cent While the chest signs were vague, a tentative diagnosis of pneumonia was made, and the surgical opinion was that the child did not have an operative condition of the abdomen Next day his temperature was 101° F No definite signs of pneumonia was made out and the fluoroscopic and x ray examinations were negative The abdomen was still distended and there was definite rigidity of the right rectus muscle and deep tenderness The leukocyte count was 7200 with polys 83 per cent Under primary anesthesia the rigidity persisted and a mass was felt in R L Q Operation was insisted upon in this case and a ruptured gangrenous appendix with beginning peritonitis was found The child had a rather stormy convalescence, developing otitis media on the fourth day This complication of course followed his acute nasopharyngitis, and it is interesting to speculate on the connection between this infection and his appendicitis

In young children, especially when there is doubt about abdominal rigidity or a mass being present, a few whiffs of chloroform will cause sufficient relaxation to enable the examiner to settle the question Valuable time may be saved if this is done early

In this boy the diagnosis was obscured by the throat infection, and the probability was with such a history that he had pneumonia The low leukocyte count was unusual, but was more against pneumonia than appendicitis

Congenital anomalies of the gastro-intestinal canal, either of structure or position, often cause abdominal pain in children about 6 or 7 years of age Bands or other abnormalities are not infrequently found that interfere with peristalsis under certain conditions

CASE 6 C B, age 6 (April 14 1926), was born 6 weeks premature, weighing 4 lb 8 oz, a

difficult feeding case, with low fat tolerance. During his third and fourth years he had recurrent vomiting attacks one to two months apart, accompanied by fever and foul stools. His appetite was always poor. For the past year he had had attacks of pain in the epigastrium, often during breakfast, sometimes after meals, lasting 2 to 3 minutes, occasionally longer. Pain seemed severe, but as a rule the child did not cry out. The attacks at first were infrequent, but latterly coming more often. Excitement or other emotion seemed to produce the pain at times, but the particular kind of food eaten was not thought to be a factor. He seldom was nauseated and rarely vomited. X-ray showed fish-hook type of stomach and irregular outline of the duodenum which was held distinctly high. Operation on June 7, 1926, by the late Dr. George D. Stewart, revealed a peritoneal band extending from gall-bladder to the transverse mesocolon across the duodenum. This band probably caused pressure and obstruction at times with consequent pain. The membrane was removed and gastrojejunostomy performed. The boy gained 2 lb. in 9 days, and since then while not wholly free from digestive disturbances, he has had little trouble.

CASE 7. H. P., age 7 (January 27, 1933). This boy thrived rather poorly as an infant. In spite of being a hearty eater, he has always been thin, rather pale, and has had a tendency to constipation. For the past year or more he has had attacks of "stomach ache" especially if overtired. This pain would occur every 2 to 8 weeks, last a few minutes, and sometimes he would vomit his lunch. The pain was then relieved, and he would go to sleep. The pain may have been caused by dietary indiscretion on occasion, though he had a sensible diet at home.

December 16, 1932, he had acute nasopharyngitis with a temperature of 103° F. This was accompanied by rather severe, dull, abdominal pain about navel, and distention, but no tenderness or other localizing signs. An enema relieved the pain, and there has been no recurrence to date. On January 31, 1933, x-ray of gastrointestinal tract showed: (a) dilated duodenum, (b) stasis of ileum, (c) incompetent ileocecal valve and incomplete retation of descending colon, and (e) appendix not visible.

Exploratory operation was considered, but deferred in the hope that the boy would improve under medical treatment. He was given a careful general diet with extra meals, cod-liver oil and iron, and rest before eating. On this he gained 4 lb. 6 oz. in 7 weeks and has been free from pain. One may assume that the pain was due to overdistension of the duodenum.

These two children represent a group who have periodic attacks of pain. While they are not really sick, they cannot be considered entirely well and happy. They are usually undernourished, often in spite of a good appetite and without other evidences of indigestion. Constipation is the rule. Sleep is apt to be light and restless. The pain is dull, referred to umbilicus, coming on during or shortly after eating. It is often relieved by a bowel movement.

There is rarely nausea or vomiting. Tenderness is usually absent. Rigidity is not found though distention may be noted. The diagnosis can only be made by a careful x-ray study of the gastro-intestinal tract.

A third group of children should be considered, with abdominal pain characterized by allergic manifestations. Allergic conditions such as are seen in simple purpura not infrequently cause difficulties in diagnosis. A history of urticaria, erythema or purpuric eruptions should always put us on guard. Headaches also are often due to an allergic state.

CASE 8. V. K., age 8, admitted to Bellevue Hospital December 9, 1932. This child had epigastric pain sometimes shooting to R. L. Q. for the past four weeks. A diagnosis of chronic appendicitis was made, and she was operated upon December 12. A somewhat tortuous appendix, kinked in its midportion, was removed. There were several large mesenteric lymph nodes near the cecum. On December 16 a purpuric rash appeared over the left shoulder with abdominal pain. There was gross blood in urine and she vomited fresh blood. The child had Henoch's purpura which probably had begun with the onset of pain four weeks before and was responsible for her pain. Her mother subsequently recalled that she had had an attack of urticaria 3 years before.

Abdominal pain very commonly occurs in allergic conditions. Henoch's purpura has other allergic manifestations, urticaria and erythema, which usually are precursors of the purpuric eruption.

Allergy not associated with purpura sometimes causes abdominal pain which simulates appendicitis. In these cases the patient is hypersensitive to a certain food and always has pain after eating it. The skin tests are not reliable in determining the etiology.

Jaundice may be associated with abdominal pain which is hard to evaluate.

CASE 9. M. B., age 10, admitted to Bellevue Hospital October 14, 1932. Chief complaints: abdominal pain and jaundice. This girl has had repeated attacks of pain and slight jaundice. She had a large spleen and slight increase in reticulocytes. This was believed to be hemolytic jaundice with abdominal pain.

One needs every aid available to arrive at a satisfactory diagnosis, in certain cases. The following case was not diagnosed even after careful study.

CASE 10. V. P., age 12, admitted to Bellevue Hospital November 19, 1932. Pain in right and left flank of 2 months' duration. This girl was

a Greek who spoke English imperfectly, but enough to confirm the history. A careful and thorough study failed to establish the cause of her pain. She was free from pain while in bed in the hospital. Report March 15, 1933, doing well.

This girl was sent into the hospital for observation for chronic appendicitis. Her temperature and blood count were normal. She had no localizing signs in the abdomen. A gastrointestinal x-ray series showed no abnormalities of stomach or bowels. Some urinary affection was suggested possibly stone. No evidence of stone was shown in x-ray, and a complete study of the urinary tract—cystoscopy, ureteral catheterization, pyelogram—all were negative. The urine was normal. Examination for possible abnormalities of uterus or ovaries was negative.

One might resort to hysteria or a neurotic condition as the answer, but it would be far from a satisfactory explanation. Sensitive or high strung children especially, but any child at times, will complain of pain in the abdomen after eating when under some emotional stress. But this girl was phlegmatic and showed no signs of hysteria or nervousness.

The rôle of urinary disorders in relation to abdominal pain is varied. An over-distended bladder causes pain in that region and should not be overlooked. Again, a negative urine does not exclude urinary tract affections which may cause pain.

CASE 11 D R, age 9, was admitted to Bellevue Hospital during November, 1932. Her history developed the fact that for 2 years she had suffered attacks of pain in L U Q (left flank). She had been seen in O P D on account of this pain.

X-ray showed no evidence of urinary calculus. Occult spine bifida was noted which, of course could not account for the pain. The urine was negative. Further study of her urinary tract by Dr. Meredith Campbell showed definite irregularity of the kidney pelvis by skiadof shadow. There was no evidence of obstruction in the ureter. The shadow of one calyx was enlarged. Dr. Campbell believes that this may be due to pressure outside the pelvis perhaps from perinephrosis. (The kidney lesion is probably responsible for her pain.)

While pyelitis is not always accompanied by any symptoms referable to the urinary tract, at the onset pain in the ureter region may be so prominent that if on the right side, we must consider the possibility of appendicitis. Finding pus in the urine establishes the diagnosis.

Repeated attacks of abdominal pain are caused by chronic intussusception. The sausage shaped mass appears only with the attack and in the interval no evidence of it is found. Another more rare condition should be mentioned mesenteric cyst. Here a round, easily movable tumor is felt.

To attempt to catalogue all possible conditions that cause abdominal pain would

be tedious and serve no useful purpose. The cases cited will illustrate the difficulties in diagnosis and indicate the variety of affections not all abdominal, in which pain is prominent.

THE MECHANICS OF ABDOMINAL PAIN

The abdominal viscera are relatively insensitive to pain from cutting. The liver, spleen, and kidneys are not painful when diseased unless the capsule is rapidly distended. Even a gastric ulcer is insensitive on palpation, but pressure on it through the abdominal wall causes pain. Pain results when hollow viscera are distended suddenly, especially the smaller structures, ureter, bile ducts. Chronic distention of the intestines, as in celiac disease, Hirschsprung's disease is not painful. Constipation rarely causes pain. Pain arises from sudden distention of the bowel. So called gas pains are not caused by paralysis of the bowel but by inhibition of peristalsis which allows gas to accumulate and stretch the intestinal wall. Peritoneal adhesions of the gut or bands do not cause pain unless they produce a partial or complete obstruction. Hernias of the bowel are not painful unless there is definite constriction.

The abdominal viscera are supplied by the vagus nerves which when stimulated increase secretions of digestive juices and cause contraction of the bowel wall—peristalsis. The vagus also causes contraction of throat muscles, wherefore hoarseness occurs with intestinal colic. Excessive stimulation of the sensory vagus produces facial neuralgia and altered sensitivity of the upper portions of the alimentary mucosa. Stimulation of the vagus also slows the heart and relaxes the sphincters of bladder and bowel.

The vagus then has a wide range of function and distribution.

Antagonistic action is found in the sympathetic which when stimulated decreases the intestinal secretions and muscular activity.

It is an everyday observation that these subdivisions of the involuntary nervous system are affected greatly by the emotions. Anger, fear, excitement, all interfere with digestion, with normal peristalsis and so result in constipation or diarrhea.

The mesentery and mesocolon are painful when pulled or stretched, but the posterior parietal and visceral peritoneum is in the silent area. The anterior parietal peritoneum is extremely sensitive.

The anterior parietal peritoneum is supplied by the same cerebrospinal nerves as the skin and muscles of the adjoining abdominal wall. Morley, in his book "Abdominal Pain" (1931), states that visceral pain is deep-seated, dull, spasmodic, imperfectly localized—the splanchnic type—while pain due to stimulation of the afferent somatic nerve, *e.g.*, on the anterior parietal peritoneum is sharp, continuous, and accurately localized.

Conscious pain is perceived in the thalamus as a general discomfort but not actually localized unless a definite tract

the pathway for pain arising in a diseased abdominal organ, and thus we have definite localization of pain, deep tenderness, muscular rigidity, hyperalgesia of the skin, all characteristics of somatic pain.

Livingston, in his book "The Abdominal Cavity and Peritoneum," published in 1932, on the other hand, upholds the contention that the pain mechanism is a viscerogenic reflex which closely associates the abdominal viscera with specific parts of the belly wall. This reflex takes place through the intimate relation between the cerebrospinal and involuntary nerve fibers

ABDOMINAL RECORD

carries the pain stimulus to a definite area in the cortex. Thus dull, illy defined pain in the abdomen may be the result of stimuli through the involuntary nervous system, a so-called splanchnic pain, but if the impulses are carried by cerebrospinal nerves, somatic stimuli pass through the thalamus to the cortex, and a definitely localized sharp pain is felt. Splanchnic impulses stop at the thalamus.

This somatic pain mechanism Morley calls the peritoneocutaneous reflex. He believes that the cerebrospinal nerves are

supplying the viscera, skin, and abdominal walls. He points out that definite areas of hyperalgesia are found in appendicitis, ureteral and gallbladder affections. But he says it is not true that every intra-abdominal organ may be neatly assigned a position on a surface map of visceral reflex zones.

For details of these theories reference should be had to the textbooks. The recent works of Livingston and Morley from whom I have quoted are helpful.

While the complicated problems of the

mechanics of abdominal pain are not solved, study of these explanations may aid us in understanding why pain occurs under certain conditions. If we recall that the vagus supplies the throat and the alimentary tract as well, abdominal pain occurring in the course of upper respiratory infections may be better understood. Fortunately many children presenting this symptom are not surgical problems. Yet pain in the abdomen should always demand a painstaking history and careful examination of the patient. Many mistakes are due to lack of care and thoroughness. It has been said that the difference between the general practitioner and the surgical consultant is that the surgeon makes a rectal examination.

In taking the history of a patient with the symptom of abdominal pain, the character, severity, and location should be noted. The relation of pain to eating, bowel movement, allergic conditions, and respiratory infections should be studied. The daily habits of the child, his diet, his emotional life need investigation.

Other members of the family may have tendencies to digestive disturbances, *e g*, food idiosyncracies that have a bearing on the case.

A method of physical examination that is thorough should be kept in mind. The technic of examination is important. Time is well spent in gaining the confidence of the child. The examiner's hands should be warm, for spasm of the muscles is the certain reaction to placing a cold hand on the abdomen. Both hands should be used

in palpating the abdomen, for comparison. With an older child it is wise to have him point with his finger to the site of pain, then tell him to press down and find the place that hurts. By pressing down over the child's own hand voluntary spasm may be avoided. Always begin the examination away from the area of suspected tenderness.

The examination should be deliberate, unhurried and systematic. For that reason it is well to have a written outline which will serve to keep one on the track. The synopsis shown in the Abdominal Record Chart is an attempt to cover these features.

Abdominal pain in children should always put us on guard. When confronted with this symptom a possible surgical condition should not be overlooked. But every means should be used to establish the diagnosis before resorting to operation.

In considering the acute abdomen, appendicitis is the most common affection. Intestinal obstruction, including intussusception in infants, is next in importance. From the surgical standpoint the diagnostic problem is largely one of eliminating these conditions.

SUMMARY

(1) Cases illustrating various types of abdominal pain in children are related and briefly discussed.

(2) Known facts and theories of the pain mechanism are reviewed.

(3) An outline is presented for the study of abdominal pain.

112 EAST 73RD ST

A HEALTH TRAIN

The last word from Paris' sometimes tells of new styles in medicine as well as in hats and frocks. An item from the Paris correspondent of the *Journal of the A M A* says that the Nord railway has put into service a special sanitary train to be used on its lines to facilitate radiologic examination of those of its agents who are employed in small localities, distant from hospital centers. The train is composed of three special cars, one to serve for consultations and for roentgenologic examinations, a second car for the accommodation of the physician, and the corps of assistants, and a third car that serves as a waiting room. This sanitary train which functions with great success, has as its chief

objective the application of prophylactic measures against tuberculosis but it serves, at the same time, as an evacuation center and directs to suitable institutions all patients, tuberculous or otherwise, who seek a consultation. Soon after this sanitary train was put into service a train of a similar type, but even more luxuriously equipped, was constructed by the government-controlled railways. It is designed to travel over all the lines of the government railways and to visit more particularly the remote small localities in which medical organization is inadequate, to assist in giving clinical and roentgenologic examinations to the employees of the company.

BIOPSY AS AN AID TO DIAGNOSIS

S. POLLITZER, M.D.

New York, N. Y.

In no other organ of the body occur so large a number of different diseases as in the skin. Clinicians have counted, and named, more than two hundred and fifty distinct forms of skin disorders.

In as much as all these pathological conditions are dependent upon changes in a relatively few types of elementary tissues, it is obvious that a great number of different clinical forms show anatomical changes which appear strikingly alike. Frequently, only after a careful study of the relative disturbances in different classes of cells and after a careful scrutiny of the finer cell structures by means of special and differential stains are we able to point out differences in the histopathology of these diseases.

It is true, nevertheless, that in many skin diseases we can make a diagnosis almost at a glance from a single section. This is true above all in the class of tumors of the skin. Neoplasms of epithelial origin, blood, and lymph vessels, etc., commonly present a picture that is unmistakable. Thus also many of the chronic inflammatory diseases can often be recognized with certainty. However, this cannot be said of most of the acute inflammations and infectious processes.

This brings me at once to one of the main purposes of this address. The pathologist is often asked to make a diagnosis of a clinical condition from the picture presented in a section of the skin. In a great number of instances it is not possible to answer the question, "What is this?" The pathologist may be able to say that the section discloses a process of a superficial, probably infectious, origin; or that the changes indicate a chronic infection of hematogenous origin; that the case is one of a lymphoblastoma, etc. But very few diseases have so characteristic a pathology as, for instance, lichen planus, herpes zoster, or Paget's disease, that a clear cut diagnosis is possible with the inadequate material placed before us. Very often it is a matter of pure chance whether or not a given section discloses the characteristic changes.

The intensive study of the histopathology of the skin during the past forty years has

enabled us to point out features peculiar to many skin diseases; and many of these are pathognomonic. In a case seen recently clinicians were unable to decide between leprosy and syphilis. A brief inspection of a single badly prepared section enabled me to say positively that the case was not one of leprosy. It would require a volume to describe all the characteristic changes found in the various diseases. The purpose of this paper, however, is to indicate how the histologist can help the clinician to arrive at a diagnosis. Too often the clinician sends a slide to the pathologist and expects him to make a clinical diagnosis from it. This is a wholly erroneous view to take of the function of the pathologist. The clinician should not send a picture puzzle to the pathologist with the expectation that the latter will put it together to make a clinical diagnosis. Very often the pathologist is able to solve the puzzle; but often he can determine only the general group to which the picture belongs. On the other hand, by observing certain rules, he can practically always help the clinician to come to a diagnostic conclusion, even if he cannot alone make the diagnosis for the clinician. The clinician is asking for help; he should, in turn, give all the help he can to the pathologist. In short, he should act as he would in a consultation with a colleague. He should describe the lesion, note its location, the age of the patient, and the duration of the affection; he should, furthermore, set forth a differential diagnostic picture of the clinical lesions as he sees them. The question then becomes greatly simplified for the pathologist and he may safely be counted on to give the required help, provided adequate material is furnished.

Secondly, it is the common practice of the clinician to submit the specimen he has excised to the hospital pathologist. Now, it is the simple truth of which every dermatopathologist has had repeated confirmation—and the general pathologist will not dispute it—that the general pathologist is not familiar with skin pathology. Moreover, the laboratory technician seldom knows how to cut skin sections. It matters very little whether a piece of liver or of

kidney is cut in one direction or another; an interstitial nephritis or a cirrhosis of the liver can be diagnosed from a section of these organs cut in any direction. But it is quite different in the skin. I have seen sections, stained with the universal hemotoxylin eosin, cut at a surface angle of 45 degrees or more; a diagnosis from such a section is little more than a guess.

To come to a conclusion, it may be necessary to examine many sections, possibly in series, and to employ many specific stains to bring out special features of the tissues, to determine the presence of lipid elements, lime salts, glycogen, etc. The clinician may be justified in placing the responsibility of arriving at a conclusion wholly on the pathologist; but he should not handicap him at the start by making it impossible for him to study the case with every aid that progress in his field enables him to employ. He should send the entire piece of skin he has excised, not simply a section, to the pathologist. The specimen should not be allowed to lie around on the operating table for half an hour before it is placed in the fixing fluid. It should be put at once in a 10 per cent solution of formalin and forthwith sent to the pathologist. There are better fixing agents than formalin, but none is so generally useful and none will interfere less with the staining reactions.

A matter of prime importance is to

select the portion of the lesion to be examined. An ulcerating lesion, for instance, will show granulation tissue and very likely will give no clue to the real nature of the lesion. Many a malignant growth has failed of recognition because the specimen was taken from an ulcer. Whenever it is possible, the specimen for biopsy should be cut from an early stage of the lesion and it is always well to have the excised piece of tissue large enough to include at least a border of normal skin. In cutting out the specimen, the operator should be careful not to pinch, squeeze, stretch, or otherwise maul the tissues. He should *not* use a cutaneous punch. Specimens removed with a punch are always difficult to handle; they are usually oblique and bruised. Moreover, the cylindrical wound made by the punch always leaves a disfiguring scar.

In concluding this very elementary discourse which I have prepared at the request of your chairman, I wish to emphasize the fact that a diagnosis based on a histological examination has a high degree of value and that it often is the decisive factor in differential diagnosis; that a diagnosis based on a single slide is often impossible, and that the entire specimen should be placed at the disposal of the pathologist, together with the report of the clinical diagnosis.

955 PARK AVE.

A NEAT RETORT

A delicious reply to a critic of the medical profession was made by Dr. Dean Lewis of Baltimore, President of the American Medical Association, at a meeting on medical education in Chicago a few weeks ago. The critic was a nonmedical man, Justin Miller, Dean of the Duke University School of Law. Dean Miller castigated the physicians for their "strange resistance to the experimental work of psychology and a stupid unwillingness to develop the field of psychiatry." And as if that were not enough, he added: "If it be true, as has been stated to me, that from 40 to 60 per cent of all operations for appendicitis are unnecessary and that a considerable portion could be avoided by proper psychiatric diagnosis, then the public has only a little more to fear from fakirs than from physicians."

A little later Dr. Lewis was slated to speak,

and when he rose he remarked that he was interested to hear Dean Miller's discovery that half the appendicitis operations performed were unnecessary. "I'm wondering," he added, "whether he was told that by the chief psychiatrist in one of these institutions for mental cases he speaks of, or one of the inmates."

Now our bright writers and speakers are amusing themselves with the initials NRA. In an address before the Wayne County Medical Society at Detroit, M. W. Bingay, of the *Detroit Free Press*, said: "Under the oath of Hippocrates you (the medical profession) have always had an NRA code, the NRA standing for 'Never Refuse Aid.' I fear, however, in these trying times, that many of your patients have a code of their own and for them the letters NRA stand for 'Never Reward Æsculapius.'

An "Ample" Life for the Doctor

As we look over the ranks of the successful medical practitioners, we see two types standing out sharply and distinctly. One has no time for anything but his work. He "eats, drinks, and sleeps it," as we say. Art, music, politics, finance, have little interest for him; his mind is busy on some fascinating medical problem. This type of doctor is often held up for our admiration. When we meet him, we are at once overcome by an inferiority complex because our poor minds occasionally turn to a good play, a corking mystery story, a round of golf, or the crack of a bat that lines one into the bleachers.

The other type may be equally skilled, equally sure-fingered in the operating room, and equally uncanny in that magic second sight that seems to penetrate flesh and bone and find the mysterious spot of infection that is causing the mischief. Yet an hour later he is one of a happy group of lawyers, bankers, architects, or just plain business men, an ordinary human being, "grasping life as a whole" and seeing it "in the round," as the poets say it.

Both types are admirable. It is not in the province of any critic to cast a stone at either. The first type, intense, devoted, could never join in a stein song around a

table of jolly good fellows; the second type, if made to think of nothing but work all the time, would simply perish.

But many a doctor lives in a sort of middle ground. He has a feeling that he ought to give himself wholly to his work. If he takes a few hours for golf, baseball, bridge, or a dinner party, he feels guilty, and wonders "what people will think." This subject was discussed with much wisdom and good sense not long ago by Dr. Henry S. Houghton, Associate Dean of the Division of Biological Sciences of the University of Chicago and Director of the University Clinics, in an address before a western medical society. In his work with medical students he confesses he is often drawn to the one with "a budding passion to be on the debating team, or editor of the school paper, or to toot a wicked saxophone," for "there is a chance that we can help such a person to become not only a good doctor, but an interesting man, a fruitful contribution to his own society, and an effective citizen of the world." A one-sidedness that can see nothing but science "must be corrected if a balanced view of life is to be achieved."

For the doctor is more than a doctor, and the patient is more than a patient. The doctor who knows only his science is missing something essential, something vital. One of the greatest of modern mechanistic philosophers is quoted as saying that the pursuit of science as a sole end "is incompatible with the pursuit of truth, with love, with art, with spontaneous delight, with every ideal that men have hitherto cherished." The doctor is dealing with human beings and he must be human too if he is to understand them. "If he is to serve people fully, he must not only have affection for them, but he must know them," says Dean Houghton, and "the mastery of the world of feeling and emotion is to him as great a concern as the mastery of skill." The art of healing is only one part of the greater art of living, and the doctor must know the greater if he is to understand the lesser.

Voltaire goes even further. The physician, he says, "requires a grasp of all the dexterity and intricacies of all other professional classes," for "equipped in this

way, he is able to be a benefactor to the whole of society." That is a rather large order, and it might well dismay any medical aspirant, but the doctor who can be a human being too, who can understand his patient's joy, sorrow, tragedy, romance, his whole life, in fact, is just that much better fitted to bring him back into harmony with health—physical, mental, and spiritual

The "Cut-rate" Drug Store

The egg that is a trifle doubtful, the man whose character is just a bit shady, and the drug store that makes its loudest boast about its cut prices seem to have a great deal in common. The State Board of Pharmacy has had special investigators out looking into the quality of some of the things sold at such shops, and as a result the secretary of the Board some time ago issued a warning to people who patronize them. No store, of course, is perfect, but when 44 per cent of the products purchased by the investigators in these places turned out to be inferior, what are we to think?

Out of nineteen samples of witch hazel, eleven were defective. Witch hazel is used to allay inflammation, but five samples contained acetone, an irritant. Seven of twenty-four samples of hydrogen peroxide were deficient in oxygen and hence little better than so much water. Nine of twenty one kinds of mineral oil were ineffective as laxatives.

One of these "cut-rate" emporia in Buffalo recently advertised a "Personal Health Service," said to be directed by a graduate nurse read 'to help you with your health and hygienic problems.' The veiled meaning in the word "hygienic" needs no explanation. The *Bulletin* of the Erie County Medical Society correctly states that "an individual who holds herself out as qualified to give medical advice and is not a registered physician is guilty of a misdemeanor."

Combine with all this the new "racket" of counterfeiting and bootlegging the pharmaceutical products of well-known and reputable firms under false labels, and you have the best reasons in the world

to uphold, stand by, and recommend the druggist of proven worth, character, and integrity. No inspectors, no laws can keep up with rascality. No doctor's prescriptions are safe in such places. Druggists who play fast and loose with their customers' health will stop at nothing. Physicians may well cooperate with the public in patronizing the chemist who mixes conscience in with every preparation he puts up.

How Can We Cure the Oversupply of M D's?

A congestion causes trouble, whether it is an oversupply of the blood that raises a patient's temperature, or an oversupply of doctors that gives the profession a chill. In this time of depression, of course, we feel that every line is overcrowded, that we have too many lawyers, teachers, butchers, bakers, and candle-stick makers, but as a matter of fact, the cold figures show that we have one licensed physician for every 780 persons in this country, while England has one per 1,490, France has one per 1,690 and Sweden one per 2,890. We have over 156,000 doctors all told and could do with half that number and still be as well supplied as France. The sick might not receive as good care with half the present number of doctors, but the doctors would certainly make a better living, and that is the point we are discussing here. And the doctor's income concerns the patient, too, for a well-paid profession will attract a better quality of entrants than one that is paid poorly.

A cut of 50 per cent in our supply of medical men would no doubt be going too far, but some estimate that adequate medical care could be provided here by about 120,000 active physicians, making our present surplus about 35,000. No one proposes to weed out this 35,000 surplus, but the present overcrowding is blamed for fee splitting, unnecessary services, bill-padding, illegal operations, employment of runners, and compensation rackets in an address by Dr. Walter L. Biering, of Des Moines, that is published in the *A M A Bulletin*. He quotes Dean Rogers, of the Colorado University School of Law, as declaring that 'an oversupply in any

branch of learning usually results in the development of price-cutting, irregular trade practices, and a fringe of casualties, losses, and waste." Public and individual both suffer "from the existence of misfits, failures, wasted energies, and frustrated efforts."

True, we might argue that the public will itself take care of the matter by patronizing the best and leaving the incompetent to find a living elsewhere, but we know that it unfortunately does not work out that way. The public does not always exhibit the high grade of intelligence credited to it in the textbooks, and often shows a tendency instead to flock to chiropractors, faddists, cultists, and doctors, good or poor, who are natural-born salesmen.

How, then, shall we reduce the congestion? The province of Alberta, Canada, is trying to do it by a law providing that no more physicians shall be registered there until the proportion has reached the level of one to 1,200 population. But that remedy dams the tide of new knowledge flowing in from the medical schools and tends, at least, toward medical stagnation. Sweden has what Dr. Bierring calls an ideal arrangement. They calculate just how many physicians are needed, and permit only the required number to enter the medical schools. Not only that, but it seems that the government takes care of the graduates for the first two or three years in practice, locating them in outlying districts where they prepare for such posts as they may choose for themselves later. No doctors from outside Sweden are permitted to practice there, so the number is always under complete control.

It would be quite doubtful if such an autocratic plan could be put into operation here, but many feel that our medical schools ought at least to hold the reins tighter, and release fewer medical graduates upon an already overcrowded profession. Some suggest that the schools deliberately plan to "flunk" a quarter or a third of each freshman class, and then continue the weeding process during the rest of the course, and graduate a select number of the very highest quality. Trade unions have long limited the number of apprentices, or students, in order to keep

numbers down and wages up, and it is felt that the medical profession may have to do something similar.

But it need hardly be said that the survival of the fittest in the weeding-out process should not be based on the ability to pass an examination. A real physician is something more than an intellectual machine. His work calls for the finest qualities given to man, and any selective process should test the whole man, and not merely the faculties that bring a high mark in university work. This consideration, too, should reach back into the selection of the men who are to enter the medical schools. Knowledge they should have, but also intelligence, which is something more, as the greater includes the less. Natural skill and aptitude should be there, to put the knowledge to its perfect use. Personality, a great gift in any walk of life, is needed by the physician, and, above all and ruling all, character, which makes all the other gifts a blessing or a curse, according as to whether it is present or absent, like the boy's definition of salt: "It's what makes your food taste bad when there isn't any."

Another remedy, and the one best for the public, is to win the millions to scientific medical treatment who now flock to the "isms" and the cults or deluge their unhappy systems with oceans of patent medicines. The radio, the newspaper, the public school physicians, are winning these wayward ones more and more to the right path, and it may be no exaggeration to say that every doctor in practice to-day would be needed for a proper care of the nation's health. Education, then, spreading the gospel of scientific medicine, may be the key to the problem.

Where is the "Old Family Doctor?"

This celebrated and beloved character seems to be missing. He is almost obsolete, remarked Dr. Howard W. Haggard in a recent address. Wistful myths are growing up about his memory. He was a power in the town, a paragon in medical matters, an oracle, a father confessor. Babies were named after him, and his limitations "were known only to his wife and the town druggist." We may smile

at him if we like, but Dr. Haggard reminds us that at any rate his patients did not turn from him to the quacks, the cults, the faddists. They respected him. No one suggested that the old family doctors group together into a subsidized, socialized sort of practice to become servants rather than leaders of the community. They would have regarded the slightest hint of it as an insult.

Now medicine has advanced amazingly and the doctor does far more for his patients than in the old days, yet the prestige of the physician and the public regard for medicine "have not increased correspondingly," he remarks, "indeed, they seem to have declined." The reason for it, Dr. Haggard finds in the fact that the doctor has become a mere scientist, and "to the American public the scientist is not a god, but only a servant." This loss of prestige, of public regard, is an obstacle to the advancement of medicine, he holds, and the problem now is to regain them. The physician must leave his office sometime and become a factor in public affairs. "The public will appreciate the importance of medicine when it sees the physician entering into the activities of the community and becoming a leader there."

However, it appears that some of the old family doctors are still left, and one of them out in Kansas writes a letter to his son telling about the good old days. We find it in the *Journal of the Kansas Medical Society*. He compares the wonderful new surgical instruments with the ones of his time and remarks wisely that dexterous fingers and a modicum of brains are still needed. He recalls improvisations that were necessary on the spur of the moment. "We learned to make bandages with starch instead of plaster of paris and to saw off a bone in an emergency with a carpenter's saw." Once he sent a man on horseback four miles over the prairie to borrow a long tube from a baby's bottle to "catheterize a poor old nester whose functions were out of commission." It was rapidly used and swiftly returned in time for baby's next feeding! There were no telephones or automobiles, and the buggy stove burning carbon blocks was thought the last word in comfort in zero weather.

To-day the doctor in his heated sedan goes 50 miles per hour "and is back from his country call and on his second rubber of bridge before the old doctor would have been fifteen miles on his way." But to-day's doctor "has never had fifteen or twenty tow-headed potential candidates for President named after him," he has missed being the trusted adviser in time of family trouble, and "has missed the affection and loyalty that was the heritage of the old doctor."

This subject simply will not down. Dr. Dean Lewis of Baltimore, President of the American Medical Association, read a paper a few weeks ago at a medical congress in Chicago on "The Restoration of the General Practitioner," and, as some times happens, the discussion following the paper brought out some of the most stimulating ideas. In the discussion Dr. James B. Herrick, of Chicago, said that the general practitioner of the old type "had to pass" and "cannot be put back," because "the mass of medical knowledge that came on the world a few decades ago was so huge that it made it impossible for any one mind to grasp it all, or to practice in accordance with that knowledge." For that reason, "the day of the know-all and do-all doctor has passed."

But a new type of family doctor is developing, Dr. Herrick assures us, a type that will succeed, if he is qualified. He must possess knowledge that is gained not only in his years of schooling, but "by studying long and hard through the years of practice." And that, too, is not all. He must also have character, energy, and personality.

The kernel of it, then, seems to be that if we lose the Old Family Doctor, we may gain in his place the New Family Doctor, perhaps less picturesque, but far better for the family, which after all is the main point.

The Physician's Part in Politics

All lawmaking bodies and all lawmakers are undergoing a critical scrutiny just now, all over the world. Perhaps it is deserved. In Europe the distrust has reached the point where some of the governments have

been handed over to dictators. In other lands, as in France, for instance, public mutterings against the lawmakers are both loud and deep. In America our attitude has not reached any such stage as that, but it must be said that the work of our Congress and our legislatures often leaves something to be desired, especially in legislation affecting the public health. And when our lawmaking bodies come to deal with health insurance and socialized medicine, perhaps in the near future, then the interest of the medical profession will become very active and vital.

Can we say in the face of this situation that the doctor has no concern about the sort of man who shall go to Albany and Washington? True, the doctor cannot go on the stump for or against any candidate or party, but it is entirely proper for him to keep in mind the attitude of any candidate on matter affecting the public health, and to exercise his right as a free citizen to express his honest opinion at any and all times.

What brings this matter up just now is the case of a legislator in Indiana who gave his work during his campaign that he would never vote against the interests of the medical profession. Like many other politicians, he forgot his promises as soon as he was elected, and voted against the measures advocated by the profession on every occasion. Two years later he was again a candidate, and the medical society in his district made his perfidy public. He thought he was secure in his political position and told the doctors they could do their worst and go some place else! And, says the *Journal of the Indiana Medical Association* "We did go to it; we 'ganged' on this chap, with the result that primary day, for him, was a veritable Waterloo."

Now the primaries in Indiana are on again, and the legislative committees of the state and county medical societies have given their members full information about the attitude of their lawmakers on measures affecting the public health, and the doctors are being urged to give this information to all their patients and friends. The issue of campaign is above politics. It is the interest of the people's health if it gives the doctors a little

practice for the big battle against the socialization of medicine later on, then so much the better.

To "Make Motherhood Safe for Mothers"

The strong and determined attack that is being made on maternal mortality means that the death rate must soon give way and recede to lower levels. Mothers' Day this year, on May 13, was marked by the stirring slogan, "Make Motherhood Safe for Mothers," and medical societies, women's clubs, and welfare organizations are uniting in a tremendous effort to arouse the public to the fact that many maternity deaths are preventable, in other words, that many of the 16,000 women who die annually in childbirth could be saved.

A tragical state of affairs is revealed by an investigation made by the Children's Bureau of 7,380 deaths in 15 states from causes connected with maternity. The study in each state was made at the request of the State Medical Society and the information secured by physicians of the State Boards of Health or the Children's Bureau, from the attending physician or midwife. It was discovered that 9 per cent of the women had had no medical supervision at all, or only when dying. Only 54 per cent, it seems, had any prenatal care whatever, 24 per cent had poor care, and only 13 per cent had good care starting not later than the fifth month. More than half of the women had some operative procedure, and of these, 43 per cent were women the doctor had not seen before labor or before the acute emergency. In 11 per cent of the cases there had been a cesarean section. The death rate was higher for urban than for rural sections, being 7.5 and 5.5, respectively, per 1,000 live births.

It would appear as if community effort is needed to determine the local conditions and it is by this means that improvement will most likely result. In the report of the Committee on Public Health and Medical Education presented at this year's meeting of our State Society there is contained a recommendation as to the participation of the County Societies in this movement, which is deserving of the careful attention of the membership.

Correspondence

Anonymous letters will not be noticed. All communications must carry full name and address of the writer but these do not run on the back.

To the Editor

When the Gods wish to destroy they first make mad. This old proverb is quite applicable to the two editorials entitled respectively "Defeat Hitler and Alice in Wonderland" which appeared in your Journal of April 15, 1954.

The hysterical outburst against the proponents of socialized medicine is indicative of the state of panic in the minds of those who compose the editorials in question as well as of the confusion concerning the true position and temper of the rank and file of the medical profession. Aside from the merits of the issue at hand the contents expressed and the language employed detract from the dignity of the official organ of the Medical Society of the State of New York.

The doctors who are advocating socialized medicine are not the cowards the writer would have them be, on the contrary they have the courage and the clear vision to oppose those forces in organized medicine who have vested interests to protect and who apparently are willing to stoop to any method in order to maintain their entrenched position. We are a fixating, socialized nation because at least 80 per cent of the doctors in this country are earning less than \$21200 net per annum and receive an average compensation of \$100 per hour—less than the earnings of a policeman or a plumber (see William Allan Richardson, Our Post-Depression Incomes, Medical Economics April 1954). We are also championing the socialization of medicine, because we believe that it is the only way to restore medicine to a professional status, because the present system has failed the doctors as well as the public, because true preventive medicine is only possible when the doctor's interests will be benefited and not in

jured as they are today by the elimination of illness through widespread prophylaxis.

That socialized medicine has accomplished in almost miraculous result is conceded by the third editorial in the same issue entitled "Denmark Conquers Syphilis." It admits that this plague of mankind has been placed under control in that country. Has the editor overlooked the fact that Denmark doctors who have accomplished this truly beneficent result are operating under a modified form of socialized medicine? Why then is this system is capable of producing so much for the human race does the editor pray for a Clemenceau to prevent its coming?

M. L. DRAZEN, M.D.

To the Editor

Your editorials "Defeat Hitler and Alice in Wonderland" of the 15th instant deserve the highest praise and commendation of the entire medical profession.

It augurs well for the new policy you have adopted and reminds the medical profession and its true friends of the danger which threatens them from the self-appointed professional reformers and foundations who under the guise of benevolent medical philanthropies are trying to destroy the medical profession for selfish and ill-gotten gains.

The medical profession must at all times be on guard against the insidious influences of the self-appointed guardians of the public well, therefore the Buell Medical Club of Buffalo, consisting of a group of physicians of Italian extraction at their last meeting unanimously voted to commend you for your splendid editorials.

CHARLES FROVE, M.D.

THIS AND THAT

The old time country doctor who used to get his pay in potatoes, card wood, chickens, sausage and hay would find nothing to surprise him in the reports of Hospital superintendents in various parts of the country that patients are paying their bills by supplying window shades, turkeys, express service etc. Doctors and nurses are getting used to seeing former patients acting as porters, elevator operators, carpenters, seamstresses, waitresses, gardeners, painters, and what not, to square their accounts.

poverty or vice. Nor is there a lack on any doctor.

Ten thousand children—enough to fill all passenger accommodations in seven large liners—were carried in Canadian Pacific liners during 1953. Ranging from earliest infancy to ten years, the youthful travelers were usually accompanied by their parents, but a number traveled by themselves, sometimes on journeys of 5000 miles or more.

The island of Curvo, the most remote of the Azores has a single village of 600 souls dwelling at the base of an extinct volcano, which is perhaps the most archaic community in the western world. And happily so, for ruled by a council of elders and with a priest as the only physician, Curvo knows no contagion crime,

A new paper written on the New York Herald Tribune remarks crisply that "a green apple a day buys the doctor's cough."

When you want more milk in your coffee in Malta the waiter leads the goat to your table.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Physician and Patient—Duty to Warn Patient of Dangers Incidental to Operation

Recently an interesting case came before the Appellate Courts in a nearby jurisdiction in which was presented the question as to the duty that a surgeon is under to warn a patient of the dangers incident to a contemplated operation. In order to understand the ruling it is necessary to refer briefly to the facts in the case.

A woman who was apparently a golf devotee had for some time been troubled, especially when holding a golf club, by what she described as a lump in the palm of her hand. She was referred to a surgeon for advice concerning the condition. He examined her and found that about the center of the palm there were certain lumps, with a puckering of the skin near the normal creases of the hand. There was discernible a tense band about an inch and a half long extending from about the center of the hand just below the wrist, to the fourth finger. The doctor diagnosed the case as one of Dupuytren's contracture. She complained that she could not hold a golf club the way she would like to and asked the doctor whether the tissues had become contracted from playing golf. The doctor explained that the condition was a thickening and contracture of the palmar fascia, and described to her in some detail the anatomical structure of the hand. The doctor advised an operation and told the patient that her hand would further contract if no operation was performed. She inquired as to the dangers of the operation, and he told her that the treatment would be quite simple if undertaken at the time, but would be more serious if left until later. He also told her that she would have to be in the hospital for four or five days, and explained the only recognized treatment for the condition so far as he knew was operative. He did not describe to her all the possible risks, or complications that might follow such an operation.

The patient consented to the treatment recommended and entered a hospital for

the purpose. An incision was made from about the middle of the proximal part of the palm toward the base of the fourth finger. The skin was found adherent to the underlying fascia. The skin was dissected away, retracted back, and a quantity of fascia removed. After the operation a condition developed which the doctors who testified in court later in the case were at a loss to explain. The patient's second, third, and fourth fingers became contracted. The hand became swollen and painful and x-rays showed marked atrophy of the bones of her fingers, wrist and arm. Her use of the hand was fairly described as being limited to from 25 to 50 per cent.

She thereafter brought an action against the surgeon in which she sought to receive damages for her injuries on the theory that he had failed in his duty to advise her that the operation was "serious, precarious, and dangerous," and that he had failed to acquaint her with the prospect that the operation might prove unsuccessful and cause her permanent injuries. The case came on for trial and she recovered a substantial judgment based upon the said theory of the case. Upon the trial she did not seek to prove that the defendant was in any way negligent or unskillful in his treatment of the case.

An appeal was taken from the judgment on behalf of the defendant and it was contended that he had not in any way failed in his duty to the patient. The Appellate Court in a carefully considered opinion directed a reversal of the judgment of the lower court. In the opinion the duty to the patient was summarized as follows:

"The relationship of surgeon and patient is naturally one in which trust and confidence must be placed in the surgeon. His knowledge, skill and experience are not and cannot be known to the patient, and within proper limits it would seem to require that when an operation is contemplated or proposed a reasonable clear explanation of it and of the natural and expected outcome should be vouchsafed.

"It must be borne in mind, however, that when a surgeon is asked his opinion of the patient's

condition, and for his advice as to whether an operation is necessary, he is not infallibly in a position to determine as a fact whether the condition is what he thinks it to be and whether an operation is in fact necessary. His diagnosis may be wrong and honestly so.

"Nor is he able to determine whether as is pointed out in two of the cases, the constitution of the patient, or the presence of disease unknown to him might produce an untoward result. Hence, in determining the extent of his duty, and the fact of a breach of duty owing to a disregard of his responsibility, one must be careful in considering the language used, not to apply too strictly to the rule applicable where there exist actual facts, the existence of which the person owing the duty neglects at his peril."

In determining the appeal the Court adopted a very practical attitude when it cited with approval as a guide the language of a distinguished surgeon who had testified upon the trial as follows:

"I view a surgeon as one who looks upon operations as matters of serious importance, and when any patient comes to me I feel that he is placing himself in my hands and that I am advising him as to the very best procedure for him to adopt. If I start out by outlining to him the risks that attend every operation, and there are very serious risks in all operations, although they are infrequent perhaps, I think many patients would decline to have operations and so damage themselves very seriously by waiting to see what would happen without the operation. . . . The risks in an operation such as this are first of all that you might get bacterial infection of the wound. One might get tetanus; one might get gas gangrene; one might get gangrene of the finger as a result of straightening it out and so damaging the circulation. Those are very terrible complications to outline to a patient. I never saw any of them occur but they might occur."

The Court ruled that no liability could turn on simple assurances made by the doctor to the patient that she would be all right in a short time, saying in part:

"The only question of doubt in my mind arises from the statement that the plaintiff would be 'all right' in three weeks. The consensus of opinion is that a satisfactory result occurs in the vast majority of cases, though not a perfect result. But it cannot, I think, be held that such an expression is to be taken as a warranty that the operation will entirely remove or obliterate the cause of danger. It was perhaps, just as the word 'simple' is, by itself, a not completely accurate expression. But the duty of a surgeon is to be honest in fact and to express his own honest belief, and if he does so he ought not to be judged as if he had warranted a perfect cure

not found to be derelict in his duty in any meticulous criticism of his language."

The Court in summarizing its application of the law to the facts of the case stated:

"In this case, an operation was inevitable sometime, and if the disease had rapidly progressed, and an operation followed, and because of the delay was more difficult with serious results the plaintiff would no doubt have said 'If you had not advised me as you did, I would have gone on and had the operation and it would not have been so serious, and I would have had better results.' . . . Take the case of a patient having some throat or other trouble and her physician said that 'an operation should take place now as the disease is a progressive one, but you may go on for some time without an operation, will you now submit or delay it?' and the patient delayed with more serious results, could it be said that the physician would be legally liable in damages for a breach of duty?

"I cannot see that anything turns on the question as to whether the operation was an intricate or a simple one, because there is no charge that it was not skillfully performed by Dr. S. and proper attention thereafter given at the hospital. The fact that the operation was not successful was, as stated, not due to lack of care or skill.

"In the case of a patient consulting a surgeon or physician, a personal obligation exists and imposes upon the physician or surgeon on whom the patient relies because of his skill, the duty to exercise ordinary care and skill in any advice given, and if an operation, that the operation will be skillfully performed. To fasten on a physician or surgeon the obligation to discuss with his patient the possibilities and probabilities of an operation . . . in order that the patient might make an election as to when the operation shall take place, simply because of the fiduciary or confidential relationship existing between a patient and her surgeon or physician is to my mind unwarranted. . . ."

"It is quite conceivable that one surgeon might point out both sides of the question and give the patient the opportunity of electing, while another surgeon, equally careful and skillful, would not think it advisable to point out all the possibilities and probabilities and the serious consequences incidental to an operation, and to hold that if a physician or surgeon did not do so was a breach of duty would, in my opinion, be imposing upon them an unwarranted responsibility not justified by a decided authority that I have been able to find."

Explosion of X-Ray Tubes

A young woman came to the office of a doctor specializing in x-ray therapy. She complained of eruptions in both of her hands. The doctor examined her and

found that she was suffering from psoriasis. The doctor undertook to give her an x-ray treatment amounting to $\frac{1}{4}$ skin unit for each hand. No filter was used and the distance from the apparatus to the patient's hand was 8 in. The time of the treatment was to be two minutes. Several such treatments were given to her uneventfully at intervals of two weeks. Finally during the administration of such a treatment by the doctor to the patient, without warning the x-ray tube exploded, particles of glass dropped through the opening to the table below. The doctor examined the plaintiff's face, hands and her clothing to see if any glass had done her any damage, but he found no evidence of her having been struck with any broken glass.

The woman went away, apparently making no complaint, and was not seen by the doctor thereafter. He heard nothing further from the plaintiff until he received a letter from a lawyer telling him that after the patient had left his office she had gone to Europe on a trip and during the trip she had sustained painful reactions.

Suit was instituted against the doctor to recover damages charging that by reason of the negligence of the doctor permitting the x-ray tube to explode, she had sustained serious second- and third-degree burns.

The case came on for trial and at the time of trial there were no indications present on her hand to show that she had ever sustained any burns. There are, however, evidences of the original skin condition that the doctor had treated. On the trial the plaintiff told the story that she had undergone a long period of suffering due to the burns, but she failed to corroborate the said story by any medical testimony. At the close of her testimony, the Court directed a verdict in favor of the defendant.

Claimed Negligence in Performing Herniotomy

A laborer while at work lifting a large plank suffered a sudden sharp, cutting pain in his right side, and when he consulted a physician it was found that he had sustained a right indirect inguinal hernia. He was referred, as a compensation patient, to a surgeon for operation. Under a spinal anesthesia an operation was performed upon the patient, the technic used being described by the doctor in his operation report as follows:

"Four-inch inguinal incision, aponeurosis of the external oblique divided, cord mobilized, sac dissected free, transfixed with chromic, ligated, and excised. Internal oblique brought down to shelving border of Poupart's ligament with interrupted chromic gut sutures, external oblique aponeurosis brought down to Poupart's ligament just above this with interrupted chromic. Skin closed with silk worm and pincets."

The patient remained in the hospital for three weeks and during the period of convalescence he developed a minor condition of epididymitis and a slight hemotoma at the upper angle of the wound. Both of these conditions subsided before he was discharged from the hospital as cured.

The patient thereafter instituted an action against the doctor charging him with negligence in performing the operation and charging specifically that as a result of said negligence, an infection set in in the region of the wound which has caused him pain and suffering ever since.

The case was put upon the calendar and when about to be reached for trial, plaintiff's attorney made numerous attempts to secure a settlement of the matter, but the attempts were unsuccessful. When the case was called for trial, the plaintiff, or his attorney, failed to appear and judgment by default was entered in favor of the doctor.

VENEREAL DISEASE INFORMATION

For a number of years the U. S. Public Health Service has been publishing, for the information of physicians, health officers, and others, a monthly abstract journal known as "Venereal Disease Information." This publication contains usually one original article on a subject of general interest in connection with the venereal diseases and numerous abstracts from the current literature pertaining to these diseases. In the preparation of this abstract journal more than 350 of the leading medical journals of the

world are reviewed and abstracts made of the articles on this subject. The cost of "Venereal Disease Information" is only 50 cents per annum, payable in advance to the Superintendent of Documents, Government Printing Office, Washington, D. C. It is desired to remind the reader that this nominal charge represents only a very small portion of the total expense of preparation, the journal being a contribution of the Public Health Service in its program with State and local health departments directed against the venereal diseases.

[Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers]

Laboratory Medicine—A Guide for Students and Practitioners By Daniel Nicholson, M D Second Edition. Octavo of 506 pages, illustrated Philadelphia, Lea & Febiger, 1934. Cloth, \$6 50

The Practical Medicine Series—Comprising Ten Volumes on the Year's Progress in Medicine and Surgery Series, 1933 Chicago, The Year Book Publishers [c.1933] The 1933 Year Book of Urology Edited by John H Cunningham, M D 12mo of 445 pages, illustrated Cloth, \$2 25

Statistical Report of the Health of the Navy for the Year 1932—Admiralty, October, 1933, O Murray, Secretary Octavo of 144 pages. London, His Majesty's Stationery Office, 1934 Paper, 2/6

Treatment in General Practice.—By Harry Beckman M D Second Edition Octavo of 889 pages Philadelphia, W B Saunders Company, 1934 Cloth, \$10 00

Recent Advances in Vaccine and Serum Therapy.—By Alexander Fleming, and G F Petrie Octavo of 463 pages Philadelphia, P Blakiston's Son & Company, 1934 Cloth, \$4 00

The Pocket Anatomy.—By C H Tagge, M D Ninth Edition 16mo of 333 pages Baltimore, William Wood & Company, 1933 Cloth \$2 00

Aids to Pathological Technique.—By David H Haler 16mo of 187 pages Baltimore, William Wood & Company, 1933 Cloth \$1 50

Aids to Qualitative Inorganic Analysis.—By R G Austin. 16mo of 204 pages Baltimore, William Wood & Company 1933 Cloth, \$1 50

Die Intrakutane Kanninchenmethode zur Auswertung von Diphtherie-Toxin und Antitoxin.—By Claus Jensen Octavo of 211 pages, illustrated Copenhagen, Levin & Munksgaard, 1933 (Acta Pathologica et Microbiologica Scandinavica, Supplement XIV)

Bright's Disease—A Clinical Handbook for Practitioners and Senior Students By J Norman Cruickshank, Octavo of 208 pages Baltimore William Wood & Company, 1933 Cloth \$3 75

Hypertension and Nephritis.—By Arthur M Fishberg, M D Third Edition Octavo of 668 pages, illustrated Philadelphia, Lea & Febiger, 1934 Cloth

BOOKS REVIEWED

Dietetics for the Clinician.—By Milton A. Bridges, M D Octavo of 666 pages. Philadelphia, Lea & Febiger, 1933 Cloth, \$6 50

Dr Mosenhal, in his introduction to this work, says that 'The question of ideal nutrition is not a serious problem that must be thought out, designed, and adjusted for each person.' And it is to afford the clinician the means for so working, that Dr Bridges has prepared this very complete work on diets. There is an adequate discussion of the theories involved, and in presenting the pathology of the various diseases, he gives the basis or rationale for the diet he advises. The third part of the volume is given over to Pediatric.

In his discussion of diets, the author has been most minute, and he has not missed a trick, the physician will find here the material to guide him in any case he may be possibly confronted with

L C JOHNSON

Egg, Wheat or Milk-Free Diets.—With Recipes and Food Lists By Ray M Balyeat, M D, Elmer M Buxton, M D and Ralph Bowen, M D Octavo of 149 pages, illustrated Philadelphia, J B Lippincott Co [c. 1933] Cloth, \$2 50

This volume deals mostly with allergy. The general practitioner is shown how to apply dietetic rules in a scientific manner, and judge for himself, as to the merits of the system. "To help remove the pain from migraine, the wheeze and sneeze from asthma and hay fever, we offer this book," says the author, but he does more. He gives a very excellent summary not only of the subject of sensitivity, but reports of his own experience and that of his workers which cannot fail to interest and instruct one not too familiar with the details of this trend of thinking in the modern treatment of patients

L C JOHNSON

Nervous Breakdown Its Cause and Cure.—By W Beran Wolfe M D Octavo of 240 pages New York, Farrar & Rinehart, [c. 1933] Cloth, \$2 50

This book has been written with a threefold purpose, to guide the general practitioner in his treatment, to help the patient's family and friends to understand the patient's conduct and to avoid tragic errors in their counsel and aid, but primarily to help the patient to help himself. In the seven chapters the author discusses causes, symptoms, and advice to patients. Three chapters are devoted to illustrative cases and cures. The author presents his material in a dramatic fashion

because of which the cases are clean cut, interesting and instructive

The financial cost of a neurosis is stupendous consequently the earlier an adjustment can be brought about, the better it will be for the family as well as the patient. It will profit the physician to advise the relatives of a patient to read this book. In reinforcing the contacts between the patient and his physician, it makes a practical type of book to offer to a patient for study, and is very much worth while for the physician's perusal

HAROLD R MERWARTH

The Technic of Local Anesthesia.—By Arthur E Hertzler, M D Fifth Edition. Octavo of 292 pages, illustrated St Louis, C V Mosby Company, 1933 Cloth, \$5 00

In this new edition the author covers the field of local, spinal, and regional anesthesia in a masterly manner. Every region of the human body is included in the treatise, and detailed, well illustrated descriptions of the technic are given in the corresponding chapters. It is a great satisfaction to read a text book as devoid of unnecessary phraseology and as rich in practical advice as this one

GEORGE WEBB

A Manual of Diseases of the Nose Throat and Ear.—By E B Gleason, M D Seventh Edition 12mo of 651 pages, illustrated Philadelphia, W B Saunders Company 1933 Cloth, \$4 50

That this manual of diseases of the ear, nose and throat has proven its value is evidenced by the fact that it is passing through its sixth edition. For a book of its limited size, the author has done admirably in keeping his text up to date. The complications of otitis media and mastoiditis which have been receiving a great deal of attention recently, are included in the revision of the section on the ear. This book serves its purpose well as a ready manual for the student and practitioner

M C MYERSON

Fundamentals of Biochemistry in Relation to Human Physiology.—By T R Parsons Fourth Edition 12mo of 435 pages illustrated Baltimore, William Wood & Company 1933 Cloth \$3 00

This volume deals with the biochemistry of food stuffs in a readable interesting style and at the same time presents the facts to date. There is an excellent chapter on the human machine which deals with energy exchange in normal metabolism. There follow chapters on enzymes, accessory food substances pig

ments, and applications of physical chemistry to physiology. Difficult subjects are presented in fine, readable, simple style. The book is highly recommended to those who wish a good, enjoyable review of the recent advances in biochemistry.

WILLIAM S. COLLENS

The Teaching of Preventive Medicine in Europe.—By Carl Prausnitz, M.D. Octavo of 180 pages, illustrated. New York, Oxford University Press, 1933. Cloth, \$3.75. (University of London, Heath Clark Lectures, 1932.)

This volume describes the steps being taken in various countries in Europe to teach preventive medicine. An introductory chapter sketches its history from early sporadic attempts to the present system of medical training in this field, postgraduate instruction, and the training of public health and social workers. Each ensuing chapter considers the method of training pursued in some particular country in Europe.

A. E. SHIPLEY

Mental Hygiene in the Community.—By Clara Bassett. Octavo of 394 pages. New York, The Macmillan Company, 1934. Cloth, \$3.50.

This book is an excellent survey of the various ramifications of mental hygiene and contains very little original material. In her twelve chapters the author attempts to prove the need of mental hygiene in all the professions, in medicine, nursing, social agencies, delinquency and law, parental education, the school, the church, industry, and recreation, but unfortunately does not show how this need can be met. The book is difficult to read and is apt to discourage any person looking for enlightenment, but it cannot be overlooked that the author in her introduction stated, "No attempt has been made to produce new material on any of the problems discussed. The purpose was rather to correlate and to organize available data into a form which was hoped might be of practical use."

J. L. MCCARTNEY

The Practice of Surgery.—By Russell Howard, M.S., and Alan Perry, M.S. Fourth Edition. Octavo of 1338 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$10.00.

The fourth edition is amply illustrated and covers the entire field which would be demanded of a student of surgery as his qualifications for final examination.

A review of many of the special subjects considered shows a very broad-minded attitude to both the causative factors and the therapeutic means employed at the present time. Very common expressions occur, such as "such-and-such is now the procedure, but it is too early to speak finally as to the final results." In a field which is very liberally devoted to fashions in therapy, this attitude is very refreshing to the teacher of surgery and very beneficial to the student.

This volume is the product of a judicious and a well-balanced surgeon. It is well worthy of a prominent place on the bookshelf of the student as well as the practitioner of surgery.

ROBERT F. BARBER

A City Set on a Hill.—The Significance of the Health Demonstration at Syracuse, N. Y. By C. E. A. Winslow, Dr. P. H. Octavo of 367 pages, illustrated. Garden City, N. Y., Doubleday, Doran & Company, 1934. Cloth, \$3.00. (Published for the Milbank Memorial Fund.)

In this book the author diligently holds a brief for great amplification of Public Health services. Syracuse, N. Y. is described from its beginning to its final place among cities of the first class. At the time (1923) when the Milbank Fund offers to spend a half million or more dollars in order to prove its contention that "public health is purchasable," Syracuse already has a fine record. In many health activities it has been first. For example, its Tuberculosis Clinic, established in 1908 is making an enviable record; its water and milk supplies are excellently guarded, etc. Mental hygiene, and a health propaganda bureau are examples for the effects of the depression. Personnel is curtailed. The book will be read with much interest by those acquainted with the Syracuse experiment. A sequel to Winslow's book might well be written by an unbiased observer after the elapse of a five year period without Fund direction.

FREDERICK S. WETHERELL

Human Embryology and Morphology.—By Sir Arthur Keith. Fifth Edition. Octavo of 558 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$10.00.

This latest revision of this book is indeed a masterpiece and is both complete and replete with informa-

tion and illustrations which simplify, and bring to the understanding of the every day physician, the many mysterious problems of embryology that have intrigued him from his early days in medicine.

The work more than fulfills the purpose for which it was intended. At the conclusion of each chapter there are notes and extensive bibliographies.

SAMUEL ZWERLING

Handbook of Physiology.—By the late W. D. Halliburton, M.D., and R. J. S. McDowall, M.B. Thirty-third edition. Octavo of 971 pages, illustrated. Philadelphia, P. Blakiston's Son & Company [1934]. Cloth, \$5.50.

In 1896, after a number of changes in editors, the editorship of this book was assumed by Professor W. D. Halliburton, who reconstructed it and nursed it through seventeen editions in twenty-nine years. Professor McDowall's official connection with the book began in 1928 as an editorial assistant to Halliburton, since whose death he has been responsible for its contents and make-up. The book's survival over a period of eighty-six years, in the face of remarkable advancement of the science of which it treats is sufficient evidence of its intrinsic value; and it is, now, so well and widely known among practitioners of medicine that no summary or analysis of its contents is called for in a press notice of this, its thirty-third edition.

J. C. CARDWELL

The Queen Charlotte's Text-Book of Obstetrics.—By Aleck W. Bourne, M.B. and others. Third Edition. Octavo of 679 pages, illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$5.25.

This excellent textbook on obstetrics contains a vast amount of practical information, of value not only to the medical student, but to the man in practice as well. To us, however, pictures of forceps deliveries in Sim's position are not very helpful; even axis traction forceps are carried out that way—one wonders how they do it.

It is gratifying to note that, although the usual formidable methods of infant resuscitation are described and illustrated, Queen Charlotte's Staff do not use them but depend upon carbon dioxide. Legislation may be necessary to bar these obsolete methods; it appears that no textbook may be written without including them. Nearly all the early vomitings of pregnancy are said to be neurotic in origin. This pleases the reviewer, but does not coincide with general opinion. The book is a fine one, well worth reading by obstetricians.

CHARLES A. GORDON

Text-Book of Pathology.—By Robert Muir, M.D. Third Edition. Octavo of 957 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$10.00.

The third edition of this textbook affords delightful and refreshing reading to the student of pathology. The subject is treated mainly from the viewpoint of the author's practical experience and, therefore, presents the subject in a more interesting manner than is usual. The author very frankly admits the exclusion of certain subjects which, he states, are best treated by the specialist.

For the American student, however, there may be some confusion because of the different terminology and the inclusion of certain practices which are not common in this country.

The illustrations are numerous and very creditable. The book makes a very valuable addition to the library of any pathologist and progressive man in medicine.

MAX LEDERER

Paralysis in Children.—By R. G. Gordon, M.D., and M. Forrester Brown, M.D. Octavo of 328 pages, illustrated. New York, Oxford University Press, 1933. Cloth, \$4.50.

This book is divided into 3 sections. The first deals with the physiology of movements. There are many diagrams to illustrate the muscle-nerve connections. Than follows in outline form a correlation of the clinical lesion. The causes of paralysis in children, including developmental defects, injury, inflammation and tumor are discussed as well as the diagnostic significance of physical signs.

Part II is devoted to a discussion of the individual diseases as the dystrophies, poliomyelitis, and other entities associated with paralysis.

Part III covers the general factors in treatment, namely, rest, massage, electricity, reeducation of voluntary movements, and finally the operative treatment of paralyses.

This book attempts to utilize a knowledge of neurology and the principles of orthopedic therapy as applied to children and succeeds admirably in its purpose. It is clearly written, and profusely illustrated.

STANLEY S. LAMM

INCOMING PRESIDENT'S REMARKS TO THE HOUSE OF DELEGATES

ARTHUR J. BEDELL, M.D.

*Albany, N. Y.**Delivered on May 14, 1934, at the Opening of the House*

Mr. Speaker and Members of the House of Delegates:

It is with a deep sense of gratitude and appreciation that I address you this morning. Your expression of faith by electing me your President I take as an indication of your willingness to cooperate and for this I am indeed thankful. When I consider the contending forces which are at work to weaken or destroy the practice of medicine, I am conscious of my responsibility.

I pledge my allegiance to the constitution of the Medical Society of the State of New York and especially, "to extend medical knowledge and advance medical science; to elevate the standard of medical education; to secure the enactment and enforcement of just medical and public health laws; to promote friendly intercourse among physicians; to guard and foster the material interests of its members, and to protect them against imposition; and to enlighten and direct public opinion in regard to the problems of medicine and public health."

The height to which the lofty aims of our Society may rise depends upon the efforts of every member. We are in the midst of clashing factions. There are some who gaze into the distance and see visions of few obligations, little work and much pay. They, I fear, are deluded by fantastic dreams.

The sessions of the House of Delegates will give all an opportunity to express themselves and in the end I trust that the majority will rule against further

experimentation in the practice of medicine. There is no question in my mind but that the socialization of medicine eventually means the death of the patient.

There are no reasons why the profession of medicine should change its established order because of a temporary depression from which we will emerge if only given a chance. The basic underlying economic unit of our State is the home. The relations of this group have not changed, nor have the essential elements of religious life. Why then should the contacts with the sacredness of home medical service be altered?

The voices of the propagandists have been heard throughout the land. Their words are the same and their thoughts identical. There is a constant repetition of the need of some plan; that medicine must care for those who are sick; the doctors must be more equitably distributed; and that hospital and specialized service must be more readily accessible. These futile arguments are advanced at a time when a patient can reach a physician's office or have the physician come to his home more quickly than at any time in the history of this country.

I cannot agree with those who say that it is better to go somewhere than to stand still. I cannot see the logic of a program which is not based on the economic satisfaction of those who are to work under it. Nor do I feel that the appointment of another committee in our already top-heavy organization will assist in any material way to solve the national economic

riddle or the problems connected with the practice of medicine which are, as all broad-minded observers agree, mainly dependent upon unemployment.

There is no doubt in my mind that we will do more harm than good by aligning ourselves with the forces bent upon the destruction of the present system of private practice.

I know that each of you will display your usual wisdom after acquiring a complete knowledge of the uncertainties surrounding the introduction of any changes in the practice of medicine.

Regardless of any printed statement for or against the inauguration of a new system, the fact is incontrovertible that the main object of group medicine is to tie the employee to the employer.

I urge you to avoid entangling alliances and feel certain that you will not prove false to your true selves or to your constituency by accepting any resolution or procedure presented in any guise whatsoever which will change the order of the established practice until the proposed change has been thoroughly investigated and proven by actual operation to be worthy of your acceptance.

Let us constantly guard against the insidious ingrowth of socialized service of any type. Let us scrutinize every group insurance and hospitalization scheme so as to be convinced that the patient's welfare is protected and that the sick of our State are not subjected to exploitation. Incidentally do not forget that as a result of the national government's extension and too expansive private hospital construction so unfortunately advanced by propagandists, the medical profession may be further victimized.

Whenever you come in contact with those who are advocating a new system, I suggest that you inquire into the personal relationship of the proponent to the proposed measure to the end that you may see why he is trying to foist a method of unsatisfactory, unknown, unreliable medical service upon the unsuspecting and gullible public.

Very few physicians would be content to mechanically dole out pills and mechanically give advice, and even more mechani-

cally live the life of a hired servant. There is something more noble, more exalted, more satisfying, and more worthy of the true physician than just the mere serving of time for a pittance.

May the experience of the ages be with you in your deliberation.

The State Society has too many committees. They are too loosely connected to the parent organization, usurp too many functions, publish too many opinions which have not been passed upon by the legislative bodies of the Society and are, I believe, tending to retard our natural progress, for no emergency is sufficiently acute to require an immediate decision by one man or one committee.

I believe that there should be a change in the personnel of all the committees of this Society by the infusion of new blood; that is, one of the older members of the committee should be displaced by a new one. In this way we will be educating the younger men in the Society to take their part in its trained interest. I, therefore, recommend to the House of Delegates that they pass a resolution to this effect.

Gentlemen of the house, I believe that it should be clearly stated by you that no member of a committee should be permitted to address any organization on a subject under consideration by his committee without the consent of the Executive Committee.

The reports of the officers of the Society evidence careful, efficient and constructive management. I wish particularly to stress the change in appearance of the *STATE JOURNAL* and trust that during the next year even greater advances will be made to the end that the views of our State organization and its members will be clearly expressed.

I further suggest that each delegate act as a direct personal inspiration to his County Society in stimulating a greater interest in the *JOURNAL*. That a digest of the County Society activities be sent to the editor, that any gross infringement of law be reported, and that in every way the County Society be impressed with the necessity of maintaining a superior journal.

All of the members of our Society should work harder in their chosen profession to

accept the new discoveries that are proven worth while, to discard old methods which have ceased to fulfill their expectations and to give the public the benefit of their constant study and experience

When I hear so much about the old-fashioned general practitioner, I am chagrined, for there is not any member of this Society who would like to be classed in the group of men who did wonderfully well with the knowledge of fifty years ago, but who would now be considered woefully incompetent And, gentlemen, do

not forget that the propagandist wishes to have you laud the old-fashioned family practitioner so that after you have raised him on a high pedestal, the column may be smashed and the idol crumble in the dust, and from that dust the destroyers wish to have socialized medicine arise

Now, Gentlemen of the House, I ask your whole-hearted support to the end that our State Society may assume a larger role in the protection of the health of the people of the State

SPECIAL LOW FARES AND TRANSPORTATION

Arrangements to the National Meeting at Cleveland American Medical Association

The following notice has been furnished the JOURNAL by The New York Central Lines

Special reduced railroad rates, on the basis of fare and one third for the round trip under what is known as the Certificate Plan, have been authorized for the annual meeting to be held in Cleveland in June

The popular "Lake Shore Limited" leaving Grand Central Terminal at 7 45 P.M. Eastern Standard Time, will meet the needs for a comfortable overnight trip, arriving Cleveland Union

Terminal at 8 30 A.M. the following morning

Delegates and others plan to leave via the "Lake Shore." Pullman reservations and railroad tickets may be secured from J. S. McAndrew, New York Central Line who is in charge of transportation arrangements for the group traveling from New York via the New York Central Mr McAndrew may be reached by mail or phone at his office Room 1216 466 Lexington Avenue, telephone Murray Hill 2 8000, Extension 3492

A MILK BORNE FATAL THROAT EPIDEMIC

A septic sore throat epidemic in Potsdam St Lawrence County, during which there were at least 76 and probably more cases with 4 deaths is reported in *Health News* published by the New York State Department of Health The date of onset of the first known case was April 12 Of the 76 patients for whom records are available 15 became ill during the week ending April 14 51 during the week ending April 21 and 10 during the week ending April 28

Clinically the disease was characterized by severe sore throat with considerable edema in some cases complicated by quincy Cervical adenitis was a prominent symptom and cases with joint involvement were observed Throat cultures positive for hemolytic streptococci were obtained from a number of patients Only 2 of the 76 cases were among individuals less than 15 years old Thirty five patients were males and 41 were females

All but 3 of the cases thus far investigated were among persons known to have used raw milk as a beverage coming from Dealer A Two of the three remaining patients ate in restaurants where Dealer A's milk was served This dealer sold about 200 quarts of raw milk daily less than one fifth of the entire village supply Dealer A's milk came exclusively from his own herd comprising 30 milch cows

His farm was visited from April 1 to April 8 by Mrs B employed in another community where she temporarily resided and where she

had just recovered from an attack of sore throat beginning on March 12 No throat cultures were taken during her attack Mrs B claims that she had nothing to do with the milking and that she did not enter the dairy barn during her stay at the farm Her husband Mr B, was regularly employed on the farm as a milker The second and only other milker Mr C stopped working on the farm on April 2 feeling perfectly well He however became ill with sore throat on April 9 Because Dealer A was planning to go away on a trip he rehired Mr C who returned on April 16 On this day Mr B developed septic sore throat

Samples of milk were taken from 15 cows in Dealer A's herd and hemolytic streptococci were found in specimens from 4 different cows Three of these cows showed no signs of gross mastitis The fourth cow had in the middle of February a teat injury which was treated with a teat dilator This cow had a suppurative mastitis at the time of examination with pus oozing from the injured right front teat

Although the investigation of the epidemic is not completed it has been concluded that raw milk sold by Dealer A was responsible for the series of cases It also seems likely that in some manner as yet unexplained the woman who visited the farm soon after her attack of sore throat may have been the original source of infection

DRAINAGE OF THE THORACIC SPACES

HOWARD LILIENTHAL, M.D., F.A.C.S.

New York City

Thoracic surgery is a comparatively new but rapidly developing branch, and success in its application depends less upon manual dexterity than on a full understanding of physiological and mechanical principles.

The definition of a space is "a limited portion of extension; the distance between points or objects, either filled or unfilled." There are normally no empty spaces in the thorax which are not directly connected with the respiratory air current. The other so-called cavities and spaces within the chest such as the pericardial, pleural, and mediastinal, are occupied by lubricating fluid and it is only in pathological conditions that true spaces may be formed.*

The first principle of drainage is the elimination of abnormal fluid or gas, including air, so that its walls can once more become approximated. A perfect result of drainage should be the sliding movement between the walls of the space, but this result is rarely ideally achieved, and we must expect more or less impairment of movement by adhesions. When actual obliteration cannot be brought about, there may be a permanent cavity containing gas or fluid, such as an aseptic pneumothorax which may do no harm, even though it exist for years and even though there may be both gas and fluid present.

DRAINAGE OF THE PLEURA

The most frequent region which calls for drainage is the infected pleural sac, especially when there is frank suppuration.

So much has been written about empyema and its various methods of treatment that the description of well-known procedures will not be taken up here. However, in spite of all the literature on this subject only a small proportion of physicians realize what may be called the pathological mechanics of this diseased condition. For example, one hears of general empyema and sacculated empyema. Yet, general empyema is extremely rare; the author has not seen more than three or four general empyemas in his life. When present it means that the lung is com-

pressed upon its root as on a pedicle and that the pus within the pleura completely surrounds it. This can happen in infected trauma of the chest, as a gunshot wound with a quick pouring-out of fluid (blood or sanguinolent serum) which later becomes infected, or it may occur when the empyema has begun as an extremely quick development of pleuritic effusion with no time for adhesions to form around the source of infection, usually in the periphery of the lung (Fig. 1).

Most physicians have seen the mechanism of *general* empyema with gas instead of pus in cases of artificial pneumothorax induced for the collapse of the tuberculous lung. But even here adhesions usually prevent the picture from being perfect (Fig. 2).

Nearly all the large collections which are so often spoken of as general empyemas are in reality nothing more than very large sacculations in which the two pleural layers are adherent on the mediastinal side, and at the dome of the thorax and also at the base of the lung where the two layers become adherent upon the diaphragm (Fig. 2). Empyemas of this kind have probably had their origin in a suppurating point in the lung which has first produced pleural irritation and the pouring out of a considerable quantity of infected serum which later becomes pus with or without actual perforation of the pulmonary abscess.

In these cases the lung which has been pushed inward tends to adhere to the chest wall but is forced away by the increasing quantity of infected fluid. Or there may be a comparatively small empyema directly connected with a superficial abscess of the lung greater or smaller in size, the empyema, however, rapidly developing into one great pyothorax. If the collection of pus is small we have what we are all accustomed to regard as a sacculated or localized empyema and this may originate from any part of the pulmonary surface or there may even be several points of infection with as many distinct empyemas which have developed at different times and may even contain different organisms (Fig. 3).

There may be four distinct forms, designated as: (1) Peripheral empyema.

* Abscess of the lung not being included in the normal cavities or spaces of the thorax is not taken up in this paper.

(2) Mesial empyema (often miscalled mediastinal). (3) The collection of pus between the diaphragm and the lung which the author has called supraphrenic empyema. The latter has a tendency to extend mesially and upward. It is sometimes necessary to diagnose between supraphrenic empyema and subphrenic abscess. This can easily be done when the disease is on the right side—the more usual site—by introducing a little oxygen into the peritoneal cavity through a needle and then making an x-ray film with the patient up-

a case which had existed for sixteen years unsuspected, without drainage either external or by way of a bronchus.

TREATMENT OF ACUTE EMPYEMA

First, there is aspiration of a fraction of the fluid with or without attempts at disinfection by the injection of chemicals through the needle. Various substances have been used for this injection from the formalin solution of the late J. B. Murphy to the modern coal-tar dyes which are used by the phthisiologists when they wish to

Fig 1—A. General empyema. The lung compressed from all sides upon its root.
B. Large sacculated empyema, wrongly called general empyema. (From Lilienfhal, "Thoracic Surgery," W. B. Saunders Co., 1925)

right. On the left side a drink of carbonated water will produce a gastric bubble which will function in an x-ray film in the same manner as a pneumoperitoneum. Obviously sacculated empyemas which are adjacent may coalesce. (4) The fourth form is the interlobar empyema which results from infection by that part of the lung where one lobe touches another.

Far more frequently than is suspected peripheral lung abscesses of considerable size *unconnected with a bronchus* may infect the pleura.

CHRONICITY

Broadly, empyema is either acute or chronic. Acute empyema may be said to become chronic when systemic symptoms have greatly diminished, whether this is a few weeks or months, or even longer, after the inception of the disease. The chronic empyemas are usually those which have been drained although the author once saw

Fig 2—X ray film of complete pneumothorax with the lung compressed from all sides, the analogue of general empyema

get rid of a mixed infection in a tuberculous pyothorax.

Occasionally success follows this plan in the acute cases of nontuberculous disease. Of course, it cannot be considered in the light of true mechanical drainage, and yet, the mere fact that fluid is withdrawn, even though incompletely, does put it in that class of therapy.

Next to be considered is aspiration or withdrawal of most or all of the fluid with a needle or trocar and cannula, the latter being preferable because there is less danger of injuring the expanding lung. No matter how careful one may be, a certain

amount of air replacement cannot be prevented, but the author does not consider this as necessarily undesirable. On the contrary, it may be valuable especially when suction has been used because it prevents the too sudden expansion of the diseased lung. Some operators¹ have stated that airtight drainage should be very slowly accomplished (half a day). They believe that a bubble of air might prevent the complete adhesion of the visceral and parietal pleurae in the upper part of the chest which should take place in two days. As a matter of fact, however, this "upper part of

Fig. 3.—Distribution of empyema. E, Mesial empyema. F, Three sacculated empyemas, the lower one suprahrenic. (From Lilienthal, "Thoracic Surgery," W. B. Saunders Co., 1925.)

the chest" is not necessarily the upper part when the patient is recumbent; and, besides, it is only in rare instances that complete adhesion between the pleural layers can be so quickly accomplished. If there is, as often happens, a concomitant abscess of the lung, it would be impossible to secure quick adhesion. Only healthy lung can be thus expanded. The author has seldom employed suction when emptying an empyema, unless the fluid refused to flow otherwise. He reserves this aspiration for diagnostic purposes only. And here again should be emphasized the danger of infecting the deep layers of the chest wall on withdrawing the puncture needle from infected pleura or lung abscess. The author prefers to disconnect the syringe after aspiration leaving the needle in place and then, with another syringe or the same one disinfected, to inject a few minims of strong alcohol slowly as the needle is withdrawn. Phlegmonous infections of the chest wall have an extremely high mortality

mainly because they are at first deeply hidden and have reached great proportions by the time they are recognized, often too late to save life even by wide incision.

DRAINAGE THROUGH A TUBE, INTERCOSTAL, OR BY RIB RESECTION*

This is accomplished in one of two ways. The first is to make a tiny incision in the skin, insert a trocar and cannula and pass a tube through the cannula after the trocar has been withdrawn, then fastening the tube by a suture to the thoracic wall so that it may not slip out. A small rubber catheter with many fenestrations is particularly useful for this form of drainage (Fig. 4). The other method is the usual one of resecting subperiosteally a small piece of rib, clamping and dividing the neurovascular bundle and then inserting a suitable soft-rubber tube. This opening for the tube is made fairly airtight by suturing the skin of the wound at one or both ends. The tube is held in place with the usual safety pin and adhesive plaster or still better, with a piece of gauze soaked in liquid adhesive plaster. The tube does not need to go far into the chest but we must be reasonably sure that it is in a position which will permit the complete or almost complete emptying of the pleura when the patient is upright. Many forms of tubes have been invented and re-invented usually with the idea of their not entering the chest too far, but when all sides have been argued an ordinary soft tube held in place as has been described will suffice. The external part is left long and some device for preventing the entrance of large quantities of air is applied. Here, also, numerous inventions from the simplest to the most absurdly complicated have been put forth. The author is guilty of having produced some of these himself, but from long experience he has concluded that the best way is to tie a finger-cot made of very thin flexible rubber to the end of the tube and to slit the tip of the finger-cot with scissors.† Every cough or strain, or even exhalation, will permit fluid and air to come

* After any operation for thoracic drainage in a child a careful watch for scoliotic deformity during the development of the individual must be kept up, even though only a single rib has been resected. This is too often neglected because the child seems well. Brief monthly inspections should be made to make sure that the spine is not deviating. The cause of the scoliosis may be either bony adhesions between the ribs or great thickening, and fibrotic contraction of the perietal pleura.

† A glove finger is too stiff; the kind of cot which rolls upon the finger is very pliable and is best suited for this purpose.

out and every inspiration, especially a strong intake effort will collapse the walls of the valve. The popular name of flapper drain has been adopted. While the patient is unable to be up, the tube should be long enough to hang over the edge of the bed into a wide necked bottle or even a vessel on the floor. Under no circumstance should the tube pass through a cork or other stopper which would prevent the proper action of the valve. When the

phasize the point that it is best to drain at the most dependent portion of the pleural cavity, and it must be conceded that by resecting the twelfth rib one can reach the lowest level whether the patient is supine or erect, a condition which is not often the case when resection of higher ribs has been made. But fluoroscopic observations with the tube in place will reveal that the matter of 'lowest point' is not so important as one might think. I have often ob-

Fig. 4 Incorrect manner of fenestrating a catheter or other tube, the openings are all so near the inner end that the empyema has to fill to the end of the tube before actual drainage occurs. The second picture

illustrates the correct fenestration permitting almost complete emptying. (From Lilienthal, Thoracic Surgery, W. B. Saunders Co. 1925.)

patient is ambulant we use an infant's glass urinal or a hip flask which can easily be fastened to the patient's body without discomfort so long as he is not lying down (Fig. 5). Even firm, stiff-walled cavities will often eventually collapse under persistence with this form of treatment. By the way, the drainage opening into the chest should usually be a little higher than might seem effective, the dome of the diaphragm is always much higher in the chest than one would ordinarily expect. Nather and Ochsner² have the idea that by resecting the twelfth rib and passing the tube high into the chest through a small incision perfect drainage will be secured. They em-

served that adhesions will form between the diaphragm and the chest wall whether a tube of this kind emerges at a low point or not, while the difficulties of subsequent exploration of the chest will be much greater through the Nather and Ochsner wound than through a higher one. They state that this method has been employed "in all the cases of total empyema" admitted to the surgical clinic, etc. According to the author's definition of total empyema, this would not mean a great number of cases.

The drainage tube, whether intercostal or after rib resection, should never be large

enough to endanger or erode the intercostal vessels.

Should postoperative fever persist for four of five days or if it recurs later on, an x-ray examination must be made in order to disclose the possible presence of other sacculations which must in turn be treated. If more than one of these secondary pockets are disclosed a large thoracotomy should be made with or without the resection of a rib and all adhesions within

large complicating empyema. The interlobar disease is well suited to the form of drainage secured by packing with gauze immediately after it has been opened at the second stage.* Manifestly, if the interlobar empyema has become adherent to the parietal pleura, this operation can be performed in one sitting.

BILATERAL EMPYEMA

It is always a matter for careful consideration whether or not both sides should be operated upon at the same time. Ordinarily we have preferred to drain the worse side and merely aspirate the better side at the first stage. Then days or even weeks later and after repeated aspirations as they become necessary, we treat the other side by one of the operative methods here discussed: intercostal incision with closed drainage, rib resection with closed drainage, or wide rib resection with packing. Thus far the author himself has used the packing only in the small sacculated empyemas.

CHRONIC EMPYEMA

We will first consider pleural pus sacs without an opening either through the chest wall or into a bronchus. These should be drained by one of the procedures described omitting, of course, attempts at emptying by repeated aspirations. The presence of calcification within the chest wall is a serious complication because it is obvious that this will prevent drainage by interfering with pulmonary expansion so that the cavity is held rigidly open. It is these chronic cases, and I am speaking now of the nontuberculous ones, in which efforts must be made to mobilize the lung by several months of suction drainage with the flapper valve. This will succeed in some apparently hopeless cases. When it is clear, however, that nothing has been gained it becomes necessary to decorticate or to make cross-hatching incisions through the visceral pleura down to lung tissue. This must be done through a wide inter-

Fig. 5.—Ambulant patient with finger-cot drainage of empyema into child's urine bottle.
Inset A.—Detail.

the chest should be broken down, converting the chambers into a single one and continuing the drainage as just described through the original opening, or one even lower, closing the larger wound by sutures.

INTERLOBAR EMPYEMA

If this condition exists without adhesion of lung to chest wall we usually expose the region through a free intercostal wound and produce adhesions with extrapleural packings around the proposed drainage site over which the rib has been resected and evacuate the pus at a later stage. While this may seem to be an operation of considerable magnitude it is in reality not shocking and it may prevent opening into a bronchus, always a serious affair because of the production of chronicity; it will also probably prevent the development of a

* The latter method of treating empyema at a primary operation has been recently tested thoroughly in the service of Doctor John F. Connors (*Ann. Surg.* 1931, Vol. 94). Packing is, of course, one type of drainage and in some cases of empyema, especially in those not of too great size, is particularly suitable. Doctor Connors employs it even in extensive purulent pleuritis. It is necessary to resect enough ribs to get ample room for manipulation to break down adhesions when the cavity is anatomically complicated. The gauze must not be too firmly packed. It is removed on the second to the fourth day and as a rule need not be replaced. Coughing and straining are encouraged and the various complications of tube drainage are usually avoided.

costal incision preferably without resection of a rib, though it may be necessary to divide several ribs behind their angles in order to make room for intrathoracic manipulation. Decortication or cross hatching renders the lung capable of expansion by coughing or straining or by intrapharyngeal pressure with the aid of the anesthesia mask. A surprising amount of expansion will be revealed in a lung which may have been confined for many months or even for more than a year.

This part of the operation concluded, a counter incision for an airtight drain is made in the lower part of the chest in the posterior axillary line and a valve tube applied. The large wound of exposure is approximated by pericostal sutures and the soft parts sutured in the usual way.

By far the greater number of chronic empyemas are those in which drainage through the chest wall has been unsuccessful for months or even years. Here the ribs will have become shingled upon each other diminishing the capacity of the diseased half of the thorax and they will have become deformed so that they tend to be triangular instead of flat.³ These ribs are also extremely hard and difficult to cut.

Without paying any attention to the location of the old drainage fistula, the exposure as above described, by intercostal incision and multiple division of ribs along their posterior ends, will be necessary. Everything possible should be done before resorting to thoracoplastic measures for bringing the chest wall down to the lung and it is rare indeed that the latter operation will be required.

This manner of bringing the collapsed lung to the chest wall was successfully employed by the author during the World War with excellent results. About 90 per cent of the patients operated upon were passed as fit for front line duty.* This operation was new at the time and the author does not approve of regarding a "cured" patient of this kind as fit for strenuous work in the short time which has elapsed between the operation and the time of discharge from the hospital.

BRONCHIAL FISTULA COMPLICATING EMPYEMA

When there is an opening into a bronchus in chronic empyema, mobilization of the lung should be performed, and if the bron-

chial opening can be found, an incision around its circumference should be made, the bronchus pushed into the substance of the lung and sutured in place through soft pulmonary tissue. This will be successful, usually but not invariably. It should be remarked, however, that the further away from the chest wall a bronchial fistula is situated, the more likely will be its spontaneous closure.⁴ If the bronchial fistula is found to come from a chronic lung abscess the latter will have to be packed and kept open until the empyema itself is obliterated. It will then tend to close and will require operation only when a mucous lining has formed between the skin and the bronchial opening.*

DRAINAGE OF MEDIASTINUM

To refresh your memories let me say that the superior mediastinum extends from the dome of the chest to the body of the fourth thoracic vertebra behind and to the junction of the manubrium and gladiolus sterni in front. Roughly speaking the remainder of the mediastinum is divided into an anterior and posterior part. The anterior mediastinum is just below the superior in front and the posterior extends from the lower limit of the superior (the body of the fourth thoracic vertebra) down to the lower limit of the thorax. Speaking generally, the mediastinum with its contained organs lies between the two pleural sacs, but when operating either in front or behind, it should be remembered that the left pleura may cross to the right and the border of the right continue to the left of the midline. This is of enormous consequence when operating upon the mediastinum because of the danger that both pleural sacs may be simultaneously opened. Even with intrapharyngeal pneumatic pressure by the anesthesia apparatus the danger is great.[†] In the posterior mediastinum there is normally a crossing over the right pleura to the left side in the lower part of the chest. This should not ordinarily embarrass the surgeon, though it must be fully appreciated.

Suppuration or other conditions which might demand drainage of the mediastinum are not usually recognized during life, and when they are there is a tendency on the

* In acute empyema complicated by an opening into a bronchus the cause of the fistula is usually a lung abscess which should have been treated as just described but before the development of chronicity.

† This will again be referred to in treatment of pericardiotomy.

*About 50 of these cases were treated in Base Hospital 101 St. Nazaire.

part of the physician to regard the case as hopeless, although this is far from the fact. Indeed, many lives would be saved if suppurative mediastinitis were more often in the minds of the medical men as the possible cause of a number of otherwise unexplained phenomena. It is quite true that when there has been long-continued tension in the mediastinum the pressure upon the great veins produces stasis which accounts for the enlargement of these vessels in the upper chest, neck, face, and sometimes the arms; but in the acute stages there has not been time for this enlargement and the patient may easily perish before the sign appears. This is also the case with the so-called brassy cough and the vocal cord paralysis with its peculiar whispered hoarseness.

CAUSES OF SUPPURATIVE MEDIASTINITIS

Infection may originate from within the mediastinum or by extension from without. Suppuration of mediastinal lymph nodes is a not infrequent cause of mediastinitis acute or chronic and even osteomyelitis of the anterior parts of the vertebrae may extend into the posterior mediastinum usually by slow process; or osteomyelitis of the sternum may produce anterior mediastinitis. This is rarely recognized.

Other sources of infection are perforation of the esophagus by a sharp foreign body swallowed with the food, such as a fish bone or a chicken bone.* Often this is not recognized, although if the precautions were taken in every case of mediastinitis to examine by endoscope the trachobronchial region and the esophagus, the diagnosis would be more frequent. In the case of the esophagus in some rare instances drainage from within has been accomplished by merely enlarging the esophageal wound. This, however, is only possible in the more chronic cases when the mediastinitis has been localized because in the acute or fulminant the spread of infection is so rapid that only by complete drainage may life be saved.

By the way, in speaking of mediastinitis occurring from infection within the esophagus, it should be remembered that cellular tissue connecting immediately with the mediastinum runs into the neck and that infection of intrathoracic origin may have extended from the cervical regions.

* Dilation of the esophagus for stricture or obstruction has been known to produce mediastinitis.

In performing laryngectomy Crile advises two stages for the operation: the first being the aseptic mobilization of the larynx and upper trachea with gauze packing of the surrounding spaces, so that there may be blocking of the cellular tissue connecting with the mediastinum. At the second-stage removal of the larynx the danger of the progress of mediastinitis has been eliminated.

Of course, wounds inflicted through the chest wall directly into the mediastinum may become infected and produce mediastinitis, but exclusive of battle casualties these are not common.

Mesial empyema whether primary or secondary has been the cause of suppurative mediastinitis.

Dunham⁵ has stated that there were 67 cases in 531 postmortem examinations of patients who had died within four weeks of diagnosed empyema (12.2 per cent). Yet that in 3,889 cases of empyema mediastinitis was not diagnosed during life. The cases were as a rule fulminant, and x-ray examination had therefore been probably omitted. Judging by the figures quoted above, this would seem to mean that there were a large number of undiagnosed cases of mediastinal infection among the 3,889 fatal (?) empyemas; probably in the neighborhood of 330 cases.*

Not only may mediastinitis be the result of infection traveling downward from the neck, but the opposite may occur by extension upward into the neck, and it may even proceed downward below the diaphragm. From the subpleural spaces progressing into the interstitial tissues of the lung, infection may travel through the root of the lung into the mediastinum. This may occur especially in interstitial suppurative pneumonitis.

In passing let us also call to mind that air entering the interstitial spaces of the lung either from trauma of a bronchus or through a rupture of an air vesicle may produce emphysema of the mediastinum running up into the neck, down the arms, and rarely taking in a very great extent, usually bilateral, of the cellular tissues, so that it may be diagnosed on palpation by the usual crackling sounds.

This not infrequently comes about after rib fracture with tearing of the lung, whether by the above mechanism or not.

* There is some doubt whether all these 3,889 cases were fatal. The reader is referred to the original article.

In the case of a patient a number of years ago when Dr. Elsborg and the author were testing the former's original apparatus for intratracheal anesthesia in human beings, we wished to note how much pressure indicated in millimeters of mercury might be safely tolerated. The patient was a young woman who was being operated upon for appendicitis under intratracheal anesthesia and a pressure of sixty millimeters was employed. There was postoperative emphysema which within a few hours had spread over the chest, neck, arms, and face of the patient closing her eyes. Every trace of emphysema had disappeared within 48 hours. But in some cases when the emphysema becomes so great as to make pressure upon the mediastinal vessels there is danger to life and it is here that an incision through the episternal notch has been recommended by Tiegel⁶ who placed a suction cup over the incision with excellent results, the emphysema disappearing in two days. When tense pneumothorax occurs in consequence of fracture of the ribs, drainage either by valve or direct suction into the resulting pneumothorax will also relieve the emphysema which manifestly is a mediastinal complication.

OPERATIVE TREATMENT OF SUPPURATION OF MEDIASTINUM

There seems to be altogether too little realization on the part of medical men of the possibilities and the great importance of early drainage of the infected mediastinum. Usually when the author has been called to see a patient, this disease has developed so far that operation is a last resort and the resulting mortality is therefore high. For some reason there is great fear of draining either the anterior or posterior mediastinum while in reality the danger is not more than in drainage of the pleura. The operation is more complicated and more difficult but this is no reason for delay.

The anterior part of the mediastinum can be reached in three ways

- (1) Through the suprasternal notch (superior mediastinum)
- (2) Through the sternum itself
- (3) Parasternally according to the location of the infection

In the acute suppuration of the superior space the spread is apt to be rapid and the safest thing is to make drainage through

the suprasternal region. This is done through a median incision with or without the addition of a cross cut at its lower limit. The mediastinum should be entered by slow careful dissection in order that neither great vessels nor pleurae be injured. Having entered the mediastinum it will be noted that with each strain or cough the pleural membranes will approximate and the fluid between them will be forced out. A multifenestrated soft tube should be inserted as far as required and permanent suction instituted.

In the case of a soldier in the A. E. F. who had been wounded by a piece of shell the foreign body lay far down in the anterior mediastinum. There was high fever and the case looked very serious. Before deciding to split the sternum the author called the late Dr. Sidney Yankauer who was able to insert a short endoscope through the suprasternal wound and to see the missile which appeared to be outside of the pericardium but was thrown into violent motion by the pulsations of the heart. Very carefully he removed it with forceps and, not having permanent suction apparatus at hand, the author placed a tube within the mediastinum, raised the foot of the bed on 18 inch blocks, and alternately a nurse and an enlisted man made suction with a syringe every 15 minutes for three days. On the second day the patient felt well, the temperature had dropped, and he was smoking cigarettes. There was full recovery.

This is merely an example of drainage of an acutely suppurating anterior mediastinitis. In another case following an operation for substernal goiter there was infection and drainage was carried out in the same manner, but this patient was in a modern hospital where continuous mechanical suction could be applied. She recovered without ever having been in mortal danger.

It may be necessary to split a greater part of the manubrium and gladioli longitudinally with or without resection in order to gain perfect drainage (Milton's operation). One must be certain that the posterior periosteum has been divided. In any acute case the sudden audible snapping together of the pleurae when the patient strains or coughs is most striking as observed through the wound. As the wound granulates, the movements decrease and finally disappear.

It sometimes happens that the main part of the anterior mediastinal abscess lies in

such a location that it can be reached parasternally. A parasternal sagittal incision should be made, costal cartilages removed, and then careful blunt dissection performed into the infected part, always remembering that there is no certain way of telling whether the right anterior pleura may extend over to the left or the left anterior fold over to the right. (See Figs. 7, 8, and 9.)

Posterior mediastinitis may be drained by a major operation, although with less

Fig. 6.—Diagram of rib sections and exposure for posterior mediastinotomy. (From Lilienthal, "Thoracic Surgery," W. B. Saunders Co., 1925.)

danger than that of draining the anterior space. The procedure is to incise just beyond the long spinal muscles, to divide the rhomboids if the upper part of the space must be reached, and to continue downward as far as seems necessary, resecting enough ribs to afford wide access (Fig. 6). Wounds of this kind may have to be revised, because there is a strong tendency for the ends of the resected ribs to approach each other. In making a lower posterior mediastinotomy on the left side the right pleura which normally extends across the median line in this region is in danger unless great care is exercised. If this accident has occurred it will always announce itself by a characteristic sucking sound. Dissection must be careful and digital exploration to find the aorta must be made. It lies toward the left of the

vertebral bodies. In right lower posterior mediastinotomy the pleura is always in the way and must be guarded. Having reached pus, the limits of the cavity should be explored if possible and packed with gauze.

It should be repeated here that the timidity already referred to in operating for the relief of infection of the mediastinum is entirely unwarranted. To wait for a sure diagnosis may mean the loss of the patient's life. At the same time it should be emphasized that one to whom these operations are a novelty would do well to avail himself of the assistance of a trained thoracic surgeon.

DRAINAGE OF THE PERICARDIUM

The pericardial sac may contain an enormous quantity of fluid. The author has removed more than 40 oz. of pus by pericardiotomy in the case of boy of fifteen⁷ who finally made perfect and permanent recovery.*

Much has been written on pericardiotomy for drainage but the operation still remains an unusual one. A few physical principles may be of interest.

First, the opening of the pericardium through an anterior left incision with or without resection of a cartilage is not a technically difficult procedure. It is important, of course, to avoid injuring the adjacent pleura, but this can usually be accomplished by working slowly, recognizing the pleura when it is reached, and pushing it carefully out of the way. Even when we are dealing with pericarditis complicating empyema it is best to keep the drainage of the two cavities separate because the empyema is more liable to contain gangrene-producing organisms than is the pericardium. The immediate danger of suppurative pericarditis with a large amount of fluid is the production of what is known as cardiac tamponade which signifies the impeding or checking of the cardiac diastole by pressure of the fluid surrounding the heart. There are five distinct locations for operations to drain the pericardium. First, to the left of the lower part of the sternum. Second, to the right of the lower sternum. Third, through the sternum. Fourth, deliberately through the pleura (a method only for special emerg-

* Shipley, Arthur M.—Transactions of the American Surgical Society for 1927 states that the quantity of fluid in the pericardium may be as much as 7500cc. (Original reference in von Bergmann's Surgery—Translation published by Lea Brothers and Company, Philadelphia, Vol. II, p. 548, case of H. Kuemmel).

encies). Fifth, through the posterior mediastinum I have several times made the posterior exposure in the course of other operations, but I doubt that it will often be necessary as an approach for draining the pericardium.

The author's favorite route has been the one which passes to the left of the lower sternum about opposite the nipple or a little below. A sagittal incision is made from the third to the fifth interspace and a horizontal one of about equal length from the lower extremity of the first in-

may extend to the right. Therefore if possible one should identify the pleural reflection and push it carefully out of the path of operation.

It is a good procedure to suture the edge of the incised pericardium to the skin or to the other soft tissues of the chest wall so that the incision may not close prematurely. It does not seem to me to be necessary to put a permanent tube into the sac, but rather to have the patient recline and change position frequently so that drainage may be complete and constant.

Fig. 7—Average relation of pleura to the sagittal midline of the body. (From Lilienthal, "Thoracic Surgery" W. B. Saunders Co., 1925.)

Fig. 8—Interpleural space. Extreme type of the left. (From Lilienthal, "Thoracic Surgery" W. B. Saunders Co., 1925.)

cision. A triangular flap of skin and muscle is made and as much as may seem necessary of the fifth cartilage is resected with forceps or cartilage knife beginning about half an inch from the sternal border. The anterior interspaces are usually wide here, and further resection is not necessary. Through this incision the internal mammary artery can be easily found and divided after double ligation. In the presence of effusions the apical part of the heart is against the anterior chest wall so that pulsations are strongly felt as soon as the pericardium is reached. This need not alarm the operator if he proceeds slowly and carefully. The inflamed pericardium is thickened and should be carefully incised with the scalpel. There is no certainty that the pleura may not be in the way as can easily be seen by referring to Figs. 7, 8, and 9, for although normally there is a triangle of safety as shown in Fig. 2, yet the right pleura may extend to the left across the midline, or the left

I do believe, however, that occasional irrigation with saline solution through a soft tube is advisable but one must be absolutely certain that the space for reflux is greater in area than the caliber of the tube for injection, otherwise the pericardial sac may become tensely filled producing cardiac tamponade.

Pool⁸ and others have made use of Dakin's solution with apparently good results, but Beck⁹ concludes from experiments with animals that the solvent properties of the Dakin's solution should forbid its employment unless there is considerable solid exudate upon the pericardium as is found in most cases of suppurative pericarditis.

The possibility of postoperative adhesions between the heart and the pericardium is naturally present, but this is only a possibility and, from what has been observed, it is a remote one.

In one of my cases followed for more than 23 years the functional result and the physical examination including x-ray re-

real values or the truth in speech may be disclosed more by the eyes and facial expression than by words. Ordinary social intercourse is often made possible by the verbal disguise of underlying feeling.

A more important contribution is made to speech functions by the midbrain in that it contains the red nucleus as a center for the control of automatic associated movements, *i.e.*, simple and constant rhythmic movements, such as the swimming movements of fish. These are greatly modified in the production of speech but are always a necessary element. Not only are the oral muscles associated in their action but also those of the face, eyes, head, and extremities. Even the general attitude and movements of the body are related to verbal formulation and expression.

As we pass toward the newer parts of the brain, the function of structures becomes increasingly complicated. In the diencephalon, the most cephalic portion of the brain stem, are found centers for the regulation of muscular tension, the modification of automatic associated movements and for the generation of the feeling tone which underlies all emotional phenomena.

The optic thalamus is not only a center for the correlation of sensory impulses but it also elaborates a feeling tone which pervades all mental functions and colors them with pleasure or displeasure. The normal adult has learned how to avoid free expression of feeling but children may be observed to pass quickly from crying to laughter on slight provocation. The adult may weep for joy or in a tragic situation burst forth in uncontrolled hysterical laughter. Such emotional instability seems to be a part of a primitive mode of response.

In order to give expression to the infinite combinations of feeling quality the crude, mechanical activities of the oral region were hopelessly inadequate. Provision was made therefore for more delicate adjustments by the development of the diencephalon and especially through the function of the corpus striatum. The oldest part of the corpus striatum, the globus pallidum, has the capacity of reducing muscular tension. It permits that degree of relaxation which is necessary in delicate and graceful movements.

As long as animal life remained in a fluid medium, the constant, rhythmic movements served a useful purpose, but it is

necessary for the amphibians to interrupt these movements. The reptile may spend much time at rest during which the automatic undulatory movements must cease. Also it is necessary for the higher animals to be able to maintain certain postures. These changes were made possible through the development of that newer part of the corpus striatum, the neostriatum. With this equipment the bird is able to express a remarkable variety in the pitch and tone qualities of its voice. The parrot even reproduces some of the human voice sounds.

Thus far in the evolution of the brain the old plan of having the gray matter surrounded by white matter was followed. This arrangement served the purposes of primitive animal life but with the increasing need of means of contact with the external world and the greater complexity in response, provision had to be made for more and more gray matter. This was accomplished in the cerebellum and the cerebrum. In these parts of the brain because the gray matter forms the cortex of the brain substance, there is much more opportunity for expansion.

The function of the cerebellum in coordinating muscular activity is well known. Included in this is a coordination of impulses coming from the cerebral cortex with the simple and automatic mechanisms. Complex and voluntary activities are thus carried out through the harmonious action of lower centers of response. Walking is made possible without undue waste of energy. All forms of verbal expression depend upon this correlation.

The functions of the cerebrum are so varied that they must be considered separately. In general the parietal region is occupied with the finer discriminations of bodily sensations. This includes the appreciation of the qualities of roughness and texture and a recognition of the sensations which permit an object to be recognized when placed in the hand. Undoubtedly a synthesis of these sensations with that of pressure is an important element in writing.

Visual phenomena have long been associated with the functions of the occipital lobe and particularly the region of the calcarine fissure. The rather simple impressions of color, size, form, distance, and their relation in space are here synthesized and they may then be recognized. All of

this is incorporated in the material utilized in speech and is necessary in the visual perception of written language.

In the temporal lobes, associated chiefly with the higher elaborations of auditory functions stimuli from the ear are correlated and synthesized. Obviously it must be intact in order to be receptive to spoken language.

No part of the brain has been subject to so much speculation and philosophical discussion as the frontal lobes. For a long time this was considered the silent area because it yielded little clinical evidence when diseased or injured. Nevertheless, it has long been regarded as a part of the brain in which the final correlation and synthesis of sensory impressions take place. Here also occurs the selection and discharge of appropriate motor responses. Its development is coordinate with the growth of intelligence and culture. Disease of the frontal lobes leads to gross personality changes and the loss of those refinements in social contact which are characteristic of most highly civilized peoples.

Ordinarily when an attempt is made to correlate speech functions with brain physiology attention is directed to the region of the fissure of Rolando. A few decades ago, when "centers" for speech and writing were assumed and the connections between them were freely illustrated with diagrams, it seemed as though the cerebral cortex could be understood with the aid of a mechanized scheme. Better knowledge of the nervous mechanism underlying the language function has rendered useless any such simplification. As a matter of fact it was based in part upon inaccurate observations.

A brief survey of our present knowledge of the language function will indicate the complexity of the so-called higher mental or psychic processes and how the nervous system participates in them. In the beginning speech is merely a form of emotional expression. The infant's first communications are those of pleasure or discomfort. The marked emotional liability at this time suggests that the thalamus is as yet only imperfectly controlled by the cortex. The associated impulsive and generalized motor activities also seem to be the expression of poorly regulated automatic nervous mechanisms. After several months the sounds gradually become conventionalized and elaborated into words. The choice or the

construction of words is often associated with potent sensory experiences or with actual physical activities. A three-year-old child refers to a radiator as a "burniator" and to a nut-cracker as a "squeeze-nutter." In the former instance a word is constructed on the basis of a painful experience, in the latter the child is describing a process. This is much simpler than dealing with the more complex conception of the purpose of the instrument. In other words, the early forms of symbolization in language are simple, direct, and descriptive.

As mental development progresses the individual is not permitted to give free expression to his impulses and feelings. His communications are more logical and less intuitive. Language and the underlying emotions are more dissociated. Even the accessory motor activities are reduced to a minimum in the calm, deliberate linguistic productions of the mature adult. Further intellectual progress usually leads to generalization and abstraction. Any particular situation is comprehended and dealt with through the application of principles. Interest lies more in the direction of the interpretation of experience than in mere description. In contrast to this the average adult is concerned with actual and immediate situations which he discusses in concrete terms. A large proportion of his conversation is motivated by personal feeling and consists of a detailed description of daily experiences.

Whenever there is an organic or toxic condition affecting speech functions this evolution of linguistic formulation and expression is reversed. In other words, the more recently acquired and the complex and voluntary aspects of speech suffer more than the elementary and automatic. Moreover, those expressions which are highly charged with emotion—exclamations and oaths—are least often affected.

Additional insight into the subtleties of cortical activity is obtained from the observation that aphasic patients may be able to sing simple airs in time and with correct rhythm provided no attempt is made to say the words. This leads us to the consideration that musical expression is generally more closely associated with emotion than is spoken language. Children and primitive people respond to rhythm and simple melodies before they can deal with language. We have also observed that in

the evolution of the brain provision was made for the production of musical sounds before there was any means of communication like the human language.

The relation of feeling to speech functions also may be observed in persons who stutter. Their thinking and speech is thus impaired in proportion to the increase in emotional tension. Profound reactions of fear, anxiety, anger, pain, or affection give rise to disturbances in breathing, tone quality, and pitch of voice as well as to disordered articulation. Under such conditions acute attacks of stuttering may appear.* When the emotional reaction is most intense, speech may be lost.

When we study the manifestations of personality disorder in terms of altered speech function, the influence of feeling is still more evident. The compulsive neurotic may be obsessed with the recurrence of obscene expressions which he feels he has to blurt out, or he may have to repeat a verbal formula before he can proceed with other activities. The anxiety neurotic may be so troubled with difficulty in breathing that he gets into a panic, may be unable to speak and may feel he is going to die.

With the additional emotional energy which is available for the excited and elated manic patient thoughts come so rapidly that he is unable to give them full expression. He is no longer hampered by logical sequence and skips from one topic to another with only superficial association. In contrast to this the depressed patient seems overwhelmed by the labor of formulating and expressing his thoughts. His responses are delayed and monosyllabic and he may not talk at all.

It is somewhat speculative to translate into brain physiology these marked alterations in speech function. As yet the facilities for measuring the changes which may be taking place at a physiological level are very meager. It appears, however, that intense emotional conflict seriously interferes with cortical function and especially that of the prefrontal region. Clinically there is impairment of reasoning and judgment. A vicious circle is established in which there is interference with the cortical regulation of the thalamic centers of feeling tone. According to the predisposition to

illness and the general feeling attitude in the particular situation an excess of feeling leading to elation or depression may be generated. Through an excess in feeling tone resulting in elation all functions of the individual are accelerated. The facts of reality lose much of their painful content, and life's problems may be dealt with facetiously and as though they were not really worthy of serious consideration. For awhile the person plays with the facts of life and emotional tension is released through frank expression of feeling and increased motor activity.

On the other hand, if a person is gradually overwhelmed by the constant gnawing of internal conflict and by a series of painful events an excess of feeling of the depressive type pervades all mental functions and seriously interferes with cortical activities. All sensory experiences are then colored by this feeling and all functions may be retarded. Emotional tension may also be expressed in restless or agitated behavior. With general retardation there is a reduction in the amount of talk and responses may be delayed or even not obtained. This retardation is in direct proportion to the painful emotional content of the subject under consideration and the same person may be able to deal reasonably well with neutral topics.

Abnormal conditions such as these are better comprehended in psychological terms, partly because our knowledge of the related brain physiology is so deficient. The physiological aspects are more strongly suggested in the acute stages of schizophrenic disorders, especially in the catatonic state. In such a condition a patient may automatically repeat what is said just as the child learning to talk does when he fails to comprehend what has been said or has not yet learned a response. He may also meet every suggestion with an automatic negative response. When overwhelmed by his problems and distraught with conflicting impulses he may lay with his muscles tense as though all set for action and yet be unable to respond. Occasionally such a patient on recovering will tell us that he was aware of the situation but could not decide upon a course of action. In the more active phases of the acute catatonic state the responses are usually impulsive and poorly directed. They tend to be repeated in an automatic way and serve little purpose other than to give expression to dream-like experiences.

* Brown, F. W.: Stuttering: Its neurophysiological basis and probable causation, *Amer. Jour. Orthopsychiat.* 2:363.

Blanton, S.: Speech Disorders as A Medical Problem, *N. Y. State Jour. Med.* 33:215, 1933.

In the later stages of the illness when the external world has been distorted and reconstructed according to the fanciful desires of the patient a new set of symbols may be intermingled with those of the past. The symbols employed are individualistic and for awhile at least have considerable emotional value. Logical sequence in thoughts disappears as the patient loses emotional contact with his fellow beings. A word or a syllable may have value for him which is ordinarily expressed in a sentence or a paragraph. Desires are gratified through hallucinations and problems are solved by delusional formations. As the energy associated with former conflicts is thus dissipated the talk and other symbolic expressions may become empty formulae or the records of fantastic abstractions.

All of these tendencies may be observed in the so called normal individual. Thoughts and tunes tend to recur in spite of our conscious desires. Anxiety feelings are usually disclosed by the manner of speech and are the most important factors in stuttering. Some of us talk rapidly and under great pressure. Our conversation tends to be flighty and usually deals with trivial matters. Some are habitually or periodically reticent and prefer to listen. It is only by deliberate concentration that we select from irrelevant thoughts those which are appropriate for the occasion. If we attempted to give expression to every

impulse, feeling, and to all fleeting and poorly formed thoughts, our productions certainly would seem to be quite abnormal.

It would seem, therefore, that a disorder of speech is a reflection of a certain type of personality that has had difficulty in making a normal adjustment. The particular form of disorder may be related to personal problems. Emotional conflicts and the feeling of having been thwarted seriously interfere with the delicate adjustments of the cerebral cortex and the more primitive nervous tendencies then gain expression. Deliberate choice in the selection of a suitable response is gradually replaced by impulsive and automatic behavior. Speech functions may be greatly accelerated by feelings of elation or retarded by depression.

Disorders of speech may therefore be an expression of intimate personal problems. They may be determined or accentuated by actual defects in the brain, but they are also a reflection of brain physiology. In order to understand them fully and to deal with them effectively it is necessary to ascertain the underlying difficulties. Otherwise the treatment may be purely symptomatic and palliative. As yet the abnormalities in brain physiology seldom can be altered by direct approach but much can be done with the related psychological conditions and particularly the emotional factors in maladjustment.

ERRORS IN THE PRACTICE OF PHYSICAL THERAPY

LEE A. HADLEY, M.D.
Syracuse

More than seventy years ago Oliver Wendell Holmes remarked on the changes that he had witnessed during his medical practice. He further stated that causes as opposed to symptoms were coming more and more to claim the attention of the physicians of that time. These two observations have a special significance for those of us to day who are interested in the development of physical medicine. Failure is likely to follow symptomatic or empirical treatment. It is unfair to treat an undiagnosed condition by a "trial of physical therapy." Mistakes may occur in the prescription or administration of a treatment but more frequently, I believe, in a disregard of the underlying causes. In other words, every effort should be made to

establish a complete pathological picture before instituting any treatment and then base the treatment upon the indications. These are commonplace truisms which are too often disregarded.

Mrs. R. received fourteen treatments to the leg for sciatica without benefit. She was really suffering from arthritis of the spine. Another patient complained of pain in the left shoulder and received diathermy to that part. X-ray revealed malignant bone tumor of the upper end of the humerus, from which he died a short time later.

X-ray is a useful aid in the avoidance of mistakes in treatment. By this means some underlying condition may be discovered which requires surgery or other

treatment before the institution of physical therapy. In traumatic cases, the underlying bony structure must be studied. Malalignment of bony parts or bone block cannot be relieved by physical therapy. Forced movement of a joint showing destruction of articular cartilage is likely to increase the disability.

The custom of "breaking up adhesions" under an anesthetic merits *the strongest condemnation*. It is true that while the patient is insensitive to pain, the mobility may be quite free. The following day, however, the joint will likely be more firmly immobilized than before with pain increased and protective muscle spasm, particularly upon attempted motion, greater than before the forcible manipulation. The ultimate result is better if forcible interference is withheld and the patient properly treated by physical therapeutic means, even though the progress may be slow. I have seen both the shoulder and the elbow practically ankylosed as a result of forcible manipulation given to increase motion. I have aggravated cases of chronic productive arthritis by too forcibly attempting to mobilize the joints. Gentle treatment is indicated in both traumatic and arthritic joint disease.

Too active or too frequent treatment may retard recovery. The condition of Mr. C. treated for a sprain of the left sacro-iliac joint was materially aggravated by too vigorous massage of the lumbar muscles. Discontinuance of all treatments for a few days is sometimes beneficial.

Failure may likewise result from lack of cooperation on the part of the patient. Where possible, particularly in traumatic cases, the patient should carry on resistive exercises by himself between treatments. These should be definitely prescribed both as to kind and amount. Beside maintaining the patient's interest, they serve to mobilize the parts and to voluntarily develop the strength of muscles, particularly those whose activity has been limited by the injury. Splints may be necessary for support or to prevent overstretching of weakened muscles.

The persistent sinus which refuses to heal cannot be influenced by cauterizing the exuberant granulation tissue nor by local exhibition of any application to the overlying surfaces. Radiation through quartz rods, ionization, or any other treatment within the sinus itself will be un-

availing until the sequestrum, broken-down gland, or other underlying cause has been removed. X-ray of the sinus, after injection of iodized oil, is likely to prove a valuable diagnostic aid.

Radiculitis has been responsible for more failures than any other condition that I have ever treated. Many of these patients complained of pain in the arm or shoulder, sometimes with numbness of the hands. The painful parts were treated without success, the causal pathology being located at the roots of the brachial plexus. Proper therapy to the cervical region usually relieves the pain in the arm.

Paradoxically, radiculitis, is frequently overlooked because of too much attention being paid to its principal symptom—pain. This is due to a perineuritis of the nerve root where it passes through the unyielding intervertebral foramen. The condition is characterized by pain referred to the cutaneous distribution of the nerve, tenderness upon deep pressure over the nerve roots and aggravation of discomfort upon coughing, sneezing, or movement of the spine.

Clinically, the picture varies somewhat depending upon the level involved. Upper cervical radiculitis produces pain in the back of the head. Involvement from midcervical to upper thoracic, produces pain referred to the shoulder and down the arm. If the upper thoracic level is affected, the patient complains of pain in the chest. This is sometimes severe and may simulate angina, pleurisy, or intercostal neuritis. Involvement of the lower dorsal region results in abdominal pain resembling stomach or gall-bladder disease, appendicitis, renal and even pelvic disease. Carnett states that many of those patients whose pelvic or abdominal symptoms are unrelieved by repeated operations, are frequently suffering from this condition. Lumbar radiculitis, of course, produces pain in the legs. The author has mistaken this for sciatic neuritis. In most cases, the condition responds promptly to treatment applied to the proper nerve roots.

Physical therapy, then, to reach and hold its rightful place in medicine must demonstrate its value by the results which it shows after treatment of causes rather than of symptoms. For if certain colors remain in the kaleidoscopic picture of medical practice, it is only because they have proven irreplaceable in the changing pattern of therapeutic procedure.

THE FUNCTION OF A CANCER COMMITTEE OF A HOSPITAL STAFF

JOHN M SWAN, MD FACP

Rochester, N Y

The New York State Committee of the American Society for the Control of Cancer has been engaged for the past seven years in a study of the cancer situation in the State of New York. In the course of this study the Committee has reached the conclusion that an important contribution to the understanding of cancer and the care of the cancer patient can be made by a systematic examination of the tumor material which presents itself in the hospitals operating throughout the State. The Committee has suggested as the minimum membership in a Cancer Committee of a hospital staff a general surgeon, an internist, the pathologist, and the radiologist. Other members of the staff may and should be added to this basic group as the work of the Committee develops and as interest in the work of the Committee increases among the general membership of the Staff of the Hospital.

The following suggestions are made as being appropriate subjects for investigation by the Cancer Committee.

(1) A statistical study of the tumor material admitted during the year from the point of view of its relation to the total number of admissions to the hospital and its division into benign growths, precancerous lesions, and malignant growths.

Table I shows these facts for 1929, and

Table II for 1932 obtained from the records of the Park Avenue Hospital, Rochester, a general hospital of 80 adult bed capacity.

Table III summarizes these facts for the five years 1928-1932, inclusive. Attention is invited to the diminution in the percentage of cases of malignant disease during this period.

(2) A comparison of the clinical diagnosis with the pathological diagnosis.

(3) The length of time elapsing between the appearance of the first symptom and the application of the patient for advice.

Table IV illustrates the information thus obtained in cases of breast tumors.

In Case No. 19,951, the patient had noticed a lump in the right breast for a year, and three months before she applied for advice had begun to complain of pain in the left hip. The x-ray showed metastatic carcinoma of the left femur. The surgeon in charge of the case decided to remove the breast because the tumor was movable, the nipple was not retracted, and there were no palpable lymph nodes in the axilla. He thought that the removal of the breast might prevent further metastases and that some benefit might be obtained by deep roentgen therapy applied to the metastasis in the femur. The patient remained in the hospital 41 days after the operation, but died 19 days later at home without having had roentgen irradiation. The ques-

tion has been raised as to the advisability of the mastectomy in view of the bone metastasis.

Case No. 19,408 is known to be living without recurrence at the present time.

Attention should be called to the length of time the tumors had been present before these patients applied for treatment. In my opinion this is one reason why the results of surgical treatment in breast cancer are not better.

Cancer of the gastro-intestinal tract is our greatest problem. Table V gives a summary of the patients admitted in 1929 with lesions of the gastro-intestinal tract. It will be noted that the diagnosis of some of these cases is made on purely clinical grounds.

Attention is invited to case No. 19,790. The man, who was admitted with a diagnosis of postoperative adhesions had a

cholecystectomy and an appendectomy in August with a histological diagnosis of chronic cholecystitis. He was discharged convalescent 16 days after operation. This patient was readmitted in October, had a second celiotomy, and without further histological study appears in the hospital records as a case of "malignant growth (probably carcinoma) of the head of the pancreas."

The author has wondered whether it is not possible in every case of exploratory celiotomy to remove a lymph node from the neighborhood of the lesion without seriously complicating the postoperative recovery of the patient.

The author has formed the opinion that many hospital records of cases of cancer are entirely inadequate for the purpose of forming a picture of the condition subsequent to the discharge of the patient.

TABLE III.—FIVE-YEAR SUMMARY

TABLE IV.—BREAST TUMORS

Case No.	Admitting diagnosis	Final diagnosis	Sex and age	Chief symptom	Duration	Operation	Histology	Result
18,695	Carcinoma of breast	Carcinoma of breast	F. 75	Lump in the breast and hemorrhage	2 years..	2.4..... Mammectomy	Adenopapillary carcinoma	Discharged 41 days PO. Died at home 244 days later of myocardial disease
18,810	Metastatic carcinoma of axillary lymph nodes from carcinoma of breast	Metastatic carcinoma of axillary lymph nodes	F. 51	Pain in right arm and palpable axillary gland	2 years..	2.5..... Axillary dissection	Metastatic carcinoma	Discharged 4 days PO. Died at home 240 days later
18,872	Benign tumor, left breast	Adenocarcinoma, left breast	F. 40	Lump in left breast	3 months	3.5..... Radical breast amputation	Adenocarcinoma	Discharged 15 days PO. Died at home
19,102	Carcinoma of breast	Carcinoma of breast	F. 38	Tumor in right breast	6 months	4.15..... Mammectomy only	Carcinoma simplex	Discharged 3 days PO. Died at home 137 days later
19,408	Mammary adenoma	Carcinoma of breast	F. 46	Tightness and soreness in right breast	6 months	6.13..... Mammectomy	Chronic cystic mastitis with a carcinoma-tous nodule	Discharged 5 days PO.
19,951	Cancer of the breast (R), chronic arthritis	Carcinoma of breast (R), metastatic carcinoma of femur (L)	F. 67	Pain in left hip, lump in breast	3 months 1 year	9.24..... Mammectomy	Scirrhus carcinoma	Discharged 41 days PO. Died at home 19 days later
20,293	Adenofibroma, left breast	Squamous celled carcinoma, left breast	F. 40	Mass in left breast	2 years..	11.21..... Mammectomy	Squamous celled carcinoma, very rapidly growing	Discharged days PO.

Table VI shows the length of time elapsing between the appearance of symptoms and the application of the patient for advice in a group of cases admitted to the hospital during 1925. These patients are all dead with the exception of the two marked with an asterisk. Further comment on these two cases will be made later.

(4) A comparison of the diagnosis made when the patient leaves the hospital and the recorded cause of death on the death certificate of those patients who die after leaving the hospital.

Tables VII and VIII illustrate this feature. Note in Table VII Case No. 12,324, carcinoma of the bladder, confirmed by histological study in which the death certificate reads "Acute pericarditis and acute nephritis."

Case No. 11,241, in which the diagnosis was gastric ulcer, not confirmed by pathological diagnosis, in which the surgeon reported that the patient developed cancer

later, but in which the cause of death reads "Gastric hemorrhage; gastric ulcer."

Also note similar discrepancies in Cases No. 11,801, 12,033, and in Table VII, Case No. 11,566.

(5) The establishment of a follow-up system to determine the results of treatment in the hospital with particular attention to the development of recurrences, on the one hand, and permanence of results, on the other.

Table IX illustrates a method which the author has been using since 1928. The case of the patient (marked with an asterisk) who died during the fifth year proved at autopsy to be an inflammatory condition.

We have records of 2 patients who were treated in 1925, 4 in 1926, and 4 in 1927, who were living without recurrence on December 31, 1932, a total of 10 patients in which the disease has been controlled for five years or more.

TABLE V—GASTRO-INTESTINAL TRACT

Case No.	Admitting diagnosis	Final diagnosis	Sex and age	Chief symptom	Duration	Operation	Histology	Result
18,649	Intestinal obstruction	Carcinoma of the sigmoid	F 41	Impaction of feces	Indefinite	2 4 Colostomy	None	Discharged 33 days PO.
19,510	Carcinoma (suspect)	Carcinoma of the pancreas	F. 45	Epigastric pain	4 months	9 11 Celiotomy no duode removed from omentum	Adenocarcinoma	Discharged 4 days PO. Died at home 86 days later
19,836	Carcinoma of the stomach	Carcinoma of the stomach	F. 50	Loss of weight	2 years	None	None	Discharged 2 days after admission
19,997	Carcinoma of the descending colon (suspect)	Carcinoma of the descending colon	F. 54	Melena	2 years	9 25 Mikulicz	None	Died 3 days PO.
20,014	Carcinoma of the liver	Carcinoma of the liver	M 63	Pain and gastric distress	10 years	None	X-ray	Died 1 day after admission, no autopsy
19,638	Pelvic inflammatory condition	Adenocarcinoma of the sigmoid	F 42	Abdominal and back pain	2 months	7 24 Enterostomy	Adenocarcinoma	Died 105 days after admission
19,790	Postoperative adhesions	Malignant growth (probably carcinoma) of head of pancreas	M. 57	Abdominal pain and soreness, 51 days later re-admitted for vomiting. Lost 15 lb. in weight	1 year	8 17 Cholecystectomy, appendectomy 10 25 Celiotomy	Chronic Cholecystitis None	Discharged 16 days PO. Discharged 13 days PO. Died at home
20,186	Carcinoma of common bile duct	Carcinoma of the bile ducts	M 66	Jaundice	3 weeks	11 5 Exploration, hepatic duct opened and T-tube inserted, cholecystostomy and suture to wound	Carcinoma (PAH and Buffalo)	Discharged 14 days PO. Remarkable operative recovery
19,826	Intestinal obstruction	Carcinoma of the sigmoid	F. 65	Melena and intestinal obstruction	10 days	8,20 Colostomy	None	Discharged 10 days PO. Died at home 4 months later
19,153	Partial obstruction of Pylorus, probably carcinoma	Carcinoma of the stomach	F. 60	Constipation, abdominal distention loss of weight (38 lb in 4 months)	Several years	None	None	In hospital 242 days

CASE No. 11,949. Widow, aged 64 years. Admitted June 19, 1925.

Admitting diagnosis: Tumor, left breast.

Final diagnosis: Adenocarcinoma, breast.

Family history: Unsatisfactory.

Previous history: Pneumonia in 1923, five pregnancies, repair of cervix and perineum.

Condition on admission: Pain in left arm extending from axilla to fingertips since January. Three weeks ago discovered a lump in the left breast just to right of nipple. No history of injury.

Examination: Tumor in left breast to right of nipple.

Urine examination: Trace of albumin, pus.

Operation: June 19. Local anesthetic. Tumor 1 inch in diameter in upper right quadrant of left breast excised.

Pathology: Adenocarcinoma (No. 982, P.A.H.). Carcinoma (R. 205, Buffalo).

Progress: Uneventful.

Discharged: Convalescent 3 days PO.

Readmitted: Case No. 12,025, July 5, 1925.

Operation: July 6. Gas and oxygen anesthesia. Left breast, axillary contents, pectoralis major and minor muscles removed. No enlarged glands found in the axilla.

Pathology: No. 1007: Carcinoma.

Progress: Uneventful, except for nausea and vomiting. Three urine examinations; albumin in one, pus in all.

Discharged: Convalescent 12 days PO.

July 17, 1930: "Patient is alive and well and there is no recurrence."

CASE No. 11,950. Single woman, aged 30 years, an inspector. Admitted June 19, 1925.

Admitting diagnosis: Appendicitis.

Final diagnosis: Adenocarcinoma of colon.

Family history: Unsatisfactory.

Previous history: Unimportant.

Condition on admission: Seven days ago the patient began to complain of pain in the right lower abdominal quadrant, intermittent in character, and radiating across the lower half of the abdomen. There has been paroxysmal nausea but no vomiting. Anorexia has been a prominent symptom.

Examination: Abdominal wall rigid, tenderness in the right lower quadrant.

Blood examination: Leukocytes, 4,520; polymorphonuclear neutrophils, 51 per cent = 2,305;

lymphocytes, 48 per cent = 2,169; transitionals, 1 per cent.

Urine examination: Pus; otherwise negative.

Operation: At 11:20 day of admission. Gas anesthesia. Free fluid in the peritoneal cavity, ileum thickened, congested, and distended. Cecum thickened, congested, and distended. Mass 2½ inches in diameter in the hepatic flexure of the colon. Appendectomy. Resection of cecum, ascending colon, and 6 inches of the ileum. Ileocolostomy. Inspection of stomach, duodenum

* Diagnosis revised at autopsy

THE ROENTGEN DIAGNOSIS OF LESIONS OF THE SMALL INTESTINES

SAMUEL J. GOLDFARB, M.D.

From the Radiological Department of Mount Sinai Hospital, New York City

Lesions of the small bowel are manifested by evidence of partial or complete obstruction, by distortion of outline and interference with motility. Displacement is usually the result of an extrinsic process.

TECHNIC.—The small intestines may be studied with or without the aid of a contrast medium. When there is any clinical evidence of obstruction, whether partial or complete, a barium meal is contra-indicated under ordinary circumstances. In this event, the roentgen examination is made to obtain evidence of the obstruction, that is, to attempt to demonstrate dilated loops of, and fluid levels in, the intestine. To this end, exposures of the abdomen are made with the patient prone, supine, and erect (either standing or sitting, depending upon the patient's condition). It is sometimes not possible to have the patient even sit up; in this case, right and left lateral recumbent views give the desired information. The patient must not be prepared with any cathartic or enema.

When there is no clinical evidence of obstruction, a barium meal usually gives the most information. The technic of this procedure varies with the individual case. In general, the first examination should include observations 2, 4, 6, and 8 hours after taking the meal. It is sometimes desirable to repeat the examination, first to confirm the findings and second, to more carefully cover the time interval in which an abnormality is found. For a jejunal lesion, examinations at $\frac{1}{2}$, 1, $1\frac{1}{2}$, and 2 hours after ingestion may be necessary; in the presence of ileal stasis, examination at 2-hour intervals may be desirable. In other words, we do not intend to recommend a routine procedure. Each case should be individualized. Barium should reach the cecum four hours after ingestion. A delay to nine hours is suggestive, and a twenty-four-hour delay is definite evidence of an obstruction.

With the exception of lymphosarcoma, a subject which will require special discussion, practically all lesions of the small bowel result ultimately in stenosis, the sequelae of which are always partial or complete obstruction with dilation proximal to the stenosis.

The roentgen evidence of small-bowel obstruction is:

(1) The presence of dilated coils of small bowel (normally absent).

(2) The presence of fluid levels in the small bowel.

(3) Relative absence of gas in the colon.

There are all graduations in the dilatation of the small bowel depending on the degree of obstruction, its duration, and its cause, so that the appearance found may vary from an isolated loop of dilated bowel to the well-known "step-ladder" effect caused by dilated loops arranged one above the other, across the abdomen.

Further discussion of this phase of the subject will not be entered upon here.

In the absence of roentgen evidence of obstruction the administration of a contrast meal may be desirable. Since the roentgen appearance depends very largely on the individual lesion, a review of the more common lesions and the changes to be noted is now offered. Duodenal, gastrojejunal and jejunal ulcer, as well as duodenitis will not be included since they form separate chapters for study.

1. Obstruction due to mechanical causes.

- (a) Postoperative adhesions.
- (b) Gallstones, foreign body, ascaris infestation.
- (c) Spontaneous volvulus, intussusception.
- (d) Congenital bands and vessels, localized hernia into the fossa of Treitz.

2. Obstruction due to pressure from, or involvement in, an extrinsic process.

- (a) Hyperplastic glands.
- (b) Adhesion to extrinsic carcinoma.
- (c) Appendiceal abscess.

3. Herniae.

- (a) Inguinal and femoral.
- (b) Diaphragmatic.
- (c) Umbilical.

4. Intrinsic inflammatory lesions.

- (a) Tuberculosis.
- (b) Regional ileitis.
- (c) Meckel's diverticulitis.

5. Diverticula.

6. Tumors.

7. Fistulae.

8. Displacement by extra-intestinal lesions.

9. Miscellaneous.

Peritonitis.

Peritoneal metastases.

Spasticity with no demonstrable organic lesion.

(1) OBSTRUCTION DUE TO MECHANICAL CAUSES is manifested in the manner described above, that is, by delayed motility and dilatation of the gut. The degree of distension proximal to the lesion will de-

pend upon the degree of the obstruction and duration of the lesion. An etiological diagnosis can be made only occasionally and then usually in conjunction with the clinical history. An exact localization of the obstruction is usually impossible. It is only possible to place it in the upper middle or lower small intestines. Exceptions are in the duodenum and terminal 6 inches of the ileum.

At this time, only the obstruction due to *postoperative adhesions* will be discussed. Ginzburg¹ notes that practically all post-operative acute obstructions due to bands or adhesions, occur in the small bowel. He asserts that "we can state unequivocally

Fig 1—Almost complete obstruction of the ascending portion of the duodenum due to hyperplastic glands of unknown origin (operation)

that the roentgen ray frequently gave us more accurate information than the clinical signs."

As has already been noted, the site and degree of obstruction are determined, rather than the etiologic agent, so that *spontaneous volvulus, intussusception, congenital bands, obstruction resulting from an unusually free mesentery, a localized hernia of the fossa of Treitz*, such as occurs occasionally where the superior mesenteric artery crosses the flexura duodenojejunalis, are recognized by the presence of the obstruction.

The etiological diagnosis is merely a guess following upon determination of the site of the obstruction.

2 OBSTRUCTION DUE TO PRESSURE FROM, OR INVOLVEMENT IN, AN EXTRINSIC PROCESS—Three cases will be shown to illustrate this type. (1) Obstruction in the ascending portions of the duodenum due to *hyperplastic glands* (Fig 1), (2) obstruction in the ileum resulting from *adhesions to a carcinoma of the sigmoid*, with angulation of the small bowel, (3) involvement in a carcinoma of the head of the pancreas (Fig. 2).

Similar in type, for example, is the obstruction sometimes noted in the terminal ileum due to involvement in an *appendiceal abscess*. In the latter, where the obstruction is not complete, there can often be

Fig 2—Partial obstruction of the ascending portion of the duodenum due to invasion by a pancreatic carcinoma (operation)

demonstrated a narrowing or spasm in the terminal 6 inches of the ileum with moderate dilatation proximal to it, and local tenderness. A similar finding has been noted in adhesion caused by inflammation or abscesses in the pelvic organs.

3 HERNIAE are fairly common lesions of the small bowel, often resulting in obstruction. Where obstruction is not present, the hernia may be directly demonstrated (Fig 3). Scrotal herniae containing loops of small intestine are often seen following a barium meal. Strangulated irreducible herniae show, of course, the findings of obstruction and differ only in their site (Fig 4).

4 INTRINSIC INFLAMMATORY LESIONS—It is possible for any lesion of the small intestines to cause obstruction. Often, however, some lesions can be diagnosed

Fig. 3.—Diaphragmatic hernia showing the small bowel occupying most of the left side of the chest. Stomach abdominal.

Fig. 4.—Small bowel obstruction due to incarcerating inguinal hernia. Note stepladder-like appearance of the small bowel. The colon has been filled by a barium enema.

Fig. 5.—Tuberculosis of the terminal ileum and caecum ascendens, proven by operation and abdominal section. Note the marked narrowing of the last inch of the terminal ileum with marked spasticity and irregularity of the caecum ascendens. There is no obstruction to the passage of barium through the diseased area.

Fig. 6.—Regional ileitis proven by operation and pathological section. The terminal 8 inches of the ileum is cord-like in appearance, considerably narrowed and irregular. At one point there is a small pocket which would suggest beginning perforation. Proximal to this is seen a second narrowed region about 2 inches in length, the site of a similar diseased process.

before obstruction occurs, or an etiological diagnosis can be suggested. This group will now be discussed.

Tuberculosis—Tuberculous ulceration of the small bowel usually results in a spasm or irritability. Ordinarily, however, this is not the feature which is noted on the roentgenogram. The spasm usually causes a temporary obstruction, and it is the dilatation of the bowel proximal to this which is seen. The longer the delay in motility the more likely it is that a lesion is present. Ileal stasis at seven to eight hours after ingestion without barium in the large bowel, and with irregularity in the contour of the terminal ileum is suggestive evidence of the presence of ulceration in the ileum.

Fig 7—Diverticulum of the ascending portion of the duodenum

or at the ileocecal valve, especially in the presence of clinical evidence. If the cecum and ascendens are also involved, the spasm and irritability are seen in this part of the bowel. The persistent irregular filling or lack of filling of the cecum and ascendens and of the terminal ileum, with stasis and moderate dilatation proximally, are very suggestive of tuberculosis (Fig 5).

Regional ileitis, so masterly described by Crohn, Ginzburg, and Oppenheimer², is a disease of the terminal ileum, and is characterized by a subacute or chronic necrotizing inflammation. It involves usually the terminal 8 inches of the ileum. The lumen of the intestine is considerably narrowed and usually leads to stenosis, associated with chronic perforation and multiple

histulae to the colon, to another coil of small intestine, or to the abdominal wall. Roentgenologically, the affected ileum is seen as a narrowed irregular streak of barium. There may be pockets suggesting ulceration and evidence of fistulous formation. The colon is not affected except by some such fistulous connection. In the 2 cases that we have seen we did not observe dilated loops proximal to the constriction nor was there a definite delay in this portion of the intestine at the six hour observation (Fig 6).

Inflammation of Meckel's Diverticulum—This condition is manifested roentgenologically only by the obstruction it produces. The clinical data are, however, of much

Fig 8—Adenocarcinoma of the distal ileum. Note irregular filling defect with partial obstruction.

more importance in the diagnosis. Soper³, for example, illustrates such a case where there was partial obstruction of the lower ileum. At the six hour examination, there was dilatation and sacculation proximal to the lesion. This was also noted twenty-four hours after ingestion of the barium meal.

5 DIVERTICULA—Diverticula have been noted, in our experience, in all parts of the small intestines, duodenum, jejunum, and ileum. They appear as outpocketings from the lumen of the bowel which often remain filled when the portion of the bowel from which they arise has emptied. The diverticula may be single or multiple and are usually congenital. Occasionally they may be traction diverticula, due to extrinsic processes (Fig 7).

6. TUMORS.—It is not the purpose of the present discussion to become involved in any pathologic considerations of the tumors occurring in the small bowel. Suffice it to say that tumors of the lymphoblastoma group are most common, and the majority of these occur in the ileum. Carcinomas are next in frequency, appearing most often in the duodenum and about equally in jejunum and ileum. Adenomas are third. Other benign tumors include carcinoids, lipomas, fibromas and accessory pancreatic tissue. Two features are to be emphasized: first, the location of the tumors, and, second, their characteristics.

Fig. 9.—Duodenal polyp. Note smooth round filling defect in duodenal bulb. This was movable fluoroscopically.

The terminal ileum is attacked much more frequently by both benign and malignant tumors, the duodenum is next in frequency, and the jejunum is relatively free (Fig. 8). Malignant tumors are larger and usually single. Benign growths are smaller, often multiple and usually polypoid.

The small intestine is not an uncommon site for metastases from primary malignancies elsewhere in the body. The most common primary sites are stomach, pancreas and uterus. The metastases usually are found in either duodenum or ileum. Metastases to the jejunum are rare.

A special consideration should be given to lymphosarcoma of the small intestines, localized or as part of a general process. Since lymphosarcoma has no fibroblastic tendencies, the growth has no tendency to constriction. On the contrary, there is a tendency to sacculation. In Hodgkin's disease and leukemia, stenosis may, or may not, occur depending upon the amount of fibrous tissue reaction that is present. Ass-

mann⁴ also calls attention to these findings. He notes that lymphosarcoma does not produce stenosis but does produce a stiffness of the walls of the bowel with ulceration which may actually result in aneurysm-like sacculations. He states that roentgenologically the small bowel appears as smooth loops at the affected site. The valvulae connivents are absent and the loop may remain filled for a long period, after the rest of the small bowel is empty. The stasis is due to infiltration of the peritoneum; consequently the loop is fixed and may remain filled for twenty-four hours.

The roentgen diagnosis of tumors of the

Fig. 10.—Fistula between jejunum and gallbladder presumably due to perforating gallstone. Gallbladder found thickened and contracted at operation, containing several small calculi.

small intestines depends upon the deformity of outline or obstruction they produce. The obstruction may either be produced by an intussusception or by encroachment upon the lumen by the growth.

Intussusception is more apt to be associated with benign tumor and spontaneous reduction is not common because these tumors are pedunculated.

Filling defects are rarely demonstrated except possibly in the terminal 6 inches of the ileum or in the region of the ileocecal valve where the ileum is more or less mobilized.

Tumors of the duodenum may be benign or malignant. Benign polyps are usually noted as filling defects in the duodenal bulb, usually smooth in outline and mov-

able (Fig. 9). Occasionally such an apparent duodenal polyp may be really a gastric polyp prolapsing through the pylorus. Malignant tumors usually produce an irregularity which, when it occurs in the bulb is indistinguishable roentgenologically from duodenal ulcer. Such a deformity has also been noted in invasion of the bulb by pancreatic carcinoma. Carcinomas of the second portion of the duodenum, carcinoma of the ampulla of Vater, and of the third portion, manifest themselves, if at all, by obstruction. In the former the diagnosis is made clinically much earlier than any definite abnormality is demonstrated in the roentgen studies.

7. FISTULAE—Fistulae are commonly noted between the duodenum and the gallbladder or other part of the biliary system (Fig. 10), between two parts of the small intestine, or between the small and large bowels. Fistulae between biliary and intestinal systems are presumably usually due to passing or passed biliary calculi, less commonly to tumors of the gallbladder involving the duodenum.

Fistulae between parts of the small bowel are usually postoperative and more rarely due to tumor. Those due to terminal ileitis have already been described. Enterocolic fistulae are most often associated with malignant tumors of the large bowel. The fistulae are usually shown during the course of the barium enema, but may be shown after a barium meal. The presence of barium-filled jejunum or duodenum during such an enema, particularly in the presence of a colonic lesion, indicates a fistula (Fig. 11).

8. DISPLACEMENT BY EXTRA-INTESTINAL LESIONS—Practically any mass reaching a sufficiently large size and close enough to the intestine, will manifest its presence by displacement of the intestines. A cyst in the head of the pancreas will often widen the duodenal curve. Displacements due to retroperitoneal masses, mesenteric and ovarian cysts and hydrosalpinx will depend upon the location of the mass. A full urinary bladder usually lifts the ileum out of the pelvis.

9. MISCELLANEOUS.—Peritonitis, whether of tuberculous or other origin, is usually manifested by an irregular paralytic ileus, so that there are seen irregularly distributed dilatations and constrictions of the small bowel. These findings we have also noted in the presence of carcinomatous

peritoneal metastases. It is in these conditions that bizarre distributions of barium in the small bowel are to be noted. The changes in tuberculosis may be due to actual peritoneal irritation, to peritoneal glands or to adhesions. These latter may occasionally produce a localized stenosis.

SUMMARY

There have been reviewed the various changes demonstrable roentgenologically in the more common lesions of the small intestines. This review has excluded duodenal ulcer and duodenitis, as well as certain postoperative states and complications such as gastrojejunal ulcer, ileostomy,

Fig. 11—Jejunocolic fistula secondary to carcinoma of the sigmoid infiltrating the jejunum. Barium injected by rectum passed directly into the jejunum from the sigmoid

etc., as forming separate material for study. It is the author's experience that roentgen study often offers the only reliable diagnostic aid in the study of small bowel lesions. Careful technic along with experienced interpretation of the fluoroscopic observations and of the roentgenograms in conjunction with the clinical findings, lead far toward a correct diagnosis.

PITRESSIN TEST IN EPILEPSY

A. WILMOT JACOBSEN, M.D.

Buffalo

It is estimated that there are in the United States a half million persons subject to epilepsy. The large size of this group of afflicted individuals has stimulated a tremendous amount of research—as evidenced by the fact that the Index Medicus contains the titles of over 4,000 articles and books on the subject published since 1900. Notwithstanding the great amount of investigation our advance in knowledge has not been startling. We do not yet know what causes epileptic seizures.

(hyperpnea), low blood calcium, low blood sugar, increased intracranial pressure, impaired intracranial circulation, increased intracranial water content.

One of the most promising fields for investigation in the light of recent findings is that of water balance. That there is some significant relationship between water balance of the body and the occurrence of epileptic seizures has been demonstrated by the clinical observations of Temple Fay and others and by the experimental studies

Chart I.—Weight chart of hysterical child, showing 13-lb weight gain when pitressin was given. There were no symptoms produced.

Within the last few years, however, we have learned a good deal about the physiological changes in the brain which may tend to increase or to decrease the number of seizures. For example, we know that the following changes will tend to produce convulsions in susceptible individuals: Poor oxygen supply to the brain, alkalosis produced by means of ingestion of alkalis or by blowing off carbon dioxide

of McQuarrie and of Gamble and Hamilton. There are other reasons for believing that water balance is important.

(1) Hippocrates noticed that the brains of epileptics were unusually moist.

All brain surgeons have noticed this excess fluid.

(2) Encephalograms show fluid in much greater amounts in the sulci and ventricles of epileptics.

(3) In status epilepticus removal of spinal fluid results in prompt recovery.

(4) Dogs can be thrown into convulsions within 4 to 8 hours after introducing water by stomach tube. The brains of these animals are found to be water-logged.

(5) The frequency and amount of urine is considerably increased during periods of

the basis of a test for epilepsy. Frequently children come under observation with a history of "spells," "fainting attacks," "weak spells," "shaking spells," "nervous fits," etc. They may be breath-holding attacks, thymus attacks, or hysterical attacks in a so-called behavior problem child. In the past, after months of inconclusive

Chart II—Weight chart of nonepileptic child, showing gain in weight when pitressin was given, followed by prompt loss when it was discontinued. Below is intake (clear columns) and output (shaded columns) of urine for each 12 hour period. Note marked diuresis when pitressin was discontinued.

convulsions as contrasted with the non-convulsive stage of the disease.

(6) Fay notes the case of a patient suffering from neurasthenia who was given a glass of milk every hour of the day. At the end of the second week convulsions occurred for the first time in the patient's history. A second series of forced fluid was followed by a similar result.

(7) Three measures often effective in reducing the number of epileptic attacks, namely fasting, ketogenic diet, and administration of large doses of acid-forming salts have in common one action—dehydration of the body.

Thus we are led to conclude that retention of fluid in the body tends to induce seizures and this fact has been used as

office visits we have usually in the end been constrained to admit such cases into the hospital only to have week after week pass without seeing a single attack. And when the child was finally sent home the parents would soon be back reporting daily spells as before. It is a well-recognized fact that change of environment may cause any of these attacks, including the epileptic seizures, temporarily to disappear. Thus we were in a dilemma, since the treatment is very different according to the diagnosis we make.

By means of the pitressin test we can cause such a child promptly to have a typical seizure provided that it is a case of epilepsy. The procedure is to give fluids to the point of establishing a positive water

balance and when water has been retained to the extent of causing an increase of body weight of 3 to 6 per cent or more, a convulsion will result. Under ordinary conditions output will keep pace with intake and no retention will result. But by making use of the antidiuretic effect of

normal individual nor in the epileptic. Only when fluids are given in sufficient quantity along with it do we precipitate an attack. Proof of this was furnished by a mistake by which a nurse gave 10 times the prescribed dose to an epileptic patient and no convulsion resulted. Later, however,

Charts III and IV.—Weight charts of epileptic children showing occurrence of seizures (S) at the height of the weight gain.

pitressin a positive water balance is readily induced.

Pitressin is a fraction of pituitrin which lacks power of stimulating smooth muscle, but which contains the antidiuretic principle, the element useful in treating diabetes insipidus. In itself pitressin cannot produce a convulsion, neither in the

when the smaller doses were given to this patient, along with extra fluid to be retained, a seizure occurred (McQuarrie and Peeler).

The practical application of the test consists in giving 300 c.c. of water every two hours and an injection of pitressin every four hours, until a positive water

balance is established. The body weight is the best indication of this. The dose is 0.2, 0.3, 0.4 c.c., and thereafter $\frac{1}{2}$ c.c. doses until a seizure occurs or until about 8 or 10 doses have been given. If a seizure occurs, no nourishment or fluids are to be given except 1 c.c. of cream per pound of body weight every four hours. This seems to be the most effective way to eliminate further seizures.

Charts I to V are typical of the reactions to this test, although usually the weight gain is not as large as in the case which is shown in Chart I. There seem to be no bad effects whatever and the children are comfortable throughout the duration of the test. There has never been any difficulty in inducing the children to take the necessary amount of fluids. In the occasional child who reacts to pitressin

Chart V—Weight chart of epileptic child showing water retention during periods when pitressin was given and occurrence of seizures (S) on two occasions when approximately 4 lb of water had been retained, as indicated by a 4 lb gain in weight.

We used the test in about 40 cases and thus far have found it reliable. The only cases where it was of no help were those few in which no positive water balance could be established, even with pitressin, and therefore the negative results could not rule out epilepsy; furthermore, two children became nauseated so that the test had to be discontinued.

with headache, vomiting, or abdominal pain, we simply discontinue the test.

The author should like to emphasize the fact that it is unnecessary to perform this test in individuals whose attacks the physician is able to observe and which can be recognized as typically epileptic in nature. But in the large number of cases where the type of "spell" is indeterminate, this test proves a valuable aid to diagnosis.

ANNOUNCEMENT

The Gynecean Hospital Institute of Gynecologic Research of the University of Pennsylvania, is conducting an intensive study of families into which congenitally malformed individuals have been born.

Special interest centers in families in which malformations have appeared in two or more

children. Physicians who have knowledge of any such families are urged to communicate with

DR DOUGLAS P MURPHY,
Gynecean Hospital Institute,
University of Pennsylvania,
Philadelphia, Pa.

Lessons of a Great Career

It was no accident or happy stroke of luck, no "influence," no pull, no genius for self-advertisement, that lifted William Henry Welch to the lofty place he held in American medicine when his splendid career closed in Baltimore on April 30th. A study of his record reveals, woven all through it in warp and woof, the golden threads of conscientious, painstaking work, the unremitting study that goes to the very roots of the matter, and never gives up until the whole truth is discovered.

To take one example, after graduating from Yale in 1870 at the age of 20, and after teaching Latin and Greek for a year, he entered the College of Physicians and Surgeons in New York. Most students of that day would consider a four-year course at Yale more than sufficient preparation. Not so young Welch. He decided that he needed further training in chemistry and returned to New Haven for a year of work in the Sheffield Scientific School. Then he came back and completed his medical course.

No doubt, most of his classmates considered themselves educated, and proceeded to the practice of medicine. But this young man felt that he was only at the beginning

of medical knowledge. He sailed for Europe, and found pathology just established and bacteriology beginning. He studied at Strasbourg, at Leipzig, at Breslau, at Vienna, at Paris, at London. It was no wonder that when he began his practice in New York he was invited to lecture in pathology at the College of Physicians and Surgeons and to undertake research at the Bellevue Hospital Medical College. When the Johns Hopkins Medical School was established in 1884, he was called to the chair of pathology, and it was said that one of his eminent European teachers recommended the appointment. It was characteristic that his new post gave him a feeling of insufficiency, and he went to Europe for another year of study.

Never enough. He must always be reaching out for more and more knowledge. The result was that he became a center and fount of inspiration for others. Students who associated with him achieved great fame. His work centered at Johns Hopkins but radiated everywhere. He helped mightily to raise the standards of American medical education, to stimulate the advance of research, hospital organization, public health work. To enumerate his degrees is to call the roll of the leading universities of the country. He was elected president of national medical and scientific bodies too numerous to list here. He was an honorary member of the distinguished medical and health organizations all over the world and was decorated by the governments of many foreign lands. His eightieth birthday, in 1930, was the occasion of a world-wide celebration such as few men in any walk of life have ever enjoyed.

It is worth remarking, too, that amid all this blaze of distinction and fanfare of acclaim, William Henry Welch kept his fine geniality, his warm clasp of the hand, his merry twinkle of the eye. He did not cultivate the icy aloofness of manner that some seem to think necessary to dignity. He was just a fellow man working with all the rest of us in the pursuit of truth. He never felt that his education was complete. He was still the student, to the very end. His life was rich with lessons for all of us.

Aviation Medicine

The rapid growth of flying makes it desirable for physicians to know something of the physical, neurological, mental, and personal qualities that are demanded of a pilot before he is permitted to risk his own and other people's lives sailing the blue. The popular lay idea is that if a pilot has good eyesight and a sense of balance, he is competent to fly a plane, but every doctor knows, of course, that any such assumption is so totally inadequate as to be almost ludicrous.

The pilot "has only God and himself to depend upon while in the skies," remarks Dr. Ralph Greene, of Jacksonville, Florida, who has had 22 years of experience in observing fliers and of flying association with some of the world's greatest airplane pilots. He has seen the tragic history of aviation turned, page by page, almost from the beginning, and has seen the majority of the pilots he has known end their careers in fatal crashes. He wishes every amateur flyer could have a placard always before his eyes warning him that "While airplanes may be fool-proof, they are not damned-fool-proof." There are old pilots, he adds, and there have been bold pilots; but there are no old and bold pilots, for the bold ones have been killed. Among the 500 scheduled air-line pilots of this country, he informs us, many of whom are engaged in night-flying, there has been for a period of five and a half years a death of one of their members at the controls of an airplane every twenty-nine and a half days.

These tragic figures show that the ill-fated pilots often may have had some defects that were not found even by the exhaustive tests of the medical examiners—some slight failure of eye, hand, heart, brain, or spirit that was enough at a speed of 200 miles an hour to tip the delicate scale of life and death. So the examiner feels that he must delve deeper and deeper into the make-up of the fine young fellow before him if he is to save him from an untimely end.

Dr. Greene's informing paper appears in the *Journal of the Florida Medical Association*, and he begins by telling us the commoner physical defects the examiner

must watch for in the would-be pilot. The candidate should be in good general health, of course, and his heart and lungs should pass the tests with flying colors. The skull and spine must have no serious defects or irregularities. The entire system should be free from diseased conditions or defects due to previous illness. The eyes, too, must meet all kinds of tests, which we will not catalogue. Private flyers are permitted to fly with correcting lenses for imperfect vision, but not commercial pilots. It is interesting to note that in his experience of many years in examining aviators Dr. Greene has found a fair number of men who were color-blind, but never a woman.

The sense of equilibrium is something every pilot must possess, yet this very sense may lead him into a fatal crash if he trusts it too implicitly. If he is seated in a revolving chair and is turned to the right with his eyes closed, and the chair is stopped, he then feels that he is turning to the left. So if he is flying blind and his plane goes into a right-hand spin, and he brings it out of the spin and into a straight-away course, he then feels as if it were in a left-hand spin, and in trying to correct it he throws it again into a right-hand spin and may end in a crash. The wise pilot, however, knows all about this, and depends on his instruments, no matter what his senses seem to tell him.

The pilot's nervous system must be ready to respond to every call and to resist every attack, and the examiner is here faced with an important and delicate task. He must watch keenly for any signs of emotional instability, which might be fatal in a critical split second. The examiner must be a neurologist as well as a doctor, and our authority here remarks that he finds that physicians and surgeons are beginning to realize that a practical working knowledge of neurology is a valuable asset to other medical and surgical efforts. The neurological examination begins as the applicant walks into the room. The way he walks, the way he stands, the way his arms swing, or do not swing, the expression of his face, all tell their story, and may reveal organic disease of the central nervous system before a word is spoken. A large

brain tumor may be present in the "silent areas" of the brain for many years without showing a single symptom, except, perhaps, absent-mindedness. The victim may light a match and then forget it till he burns his fingers, or hold a spoonful of ice-cream in his hand till it melts. These warnings go unheeded. Finally the tumor causes a violent generalized convulsive seizure in an otherwise seemingly healthy individual. It is easy to see the importance of a situation of this kind in a pilot with a dozen passengers entrusted to his skill. This is just one of the many things the examiner must watch for. Air ventriculography is invaluable in a test of this sort.

Equally important is the personality study, to size up the candidate's nervous system in relation to temperament, intelligence, and volition. His family history must be gone into, his personal history, his environment, his play life, his sex life, his education, everything, in fact, that will throw light on his disposition and personality. Even his mental attitude toward the examiner and his prying questions may be illuminating. The examiner is not so much interested in what the pilot knows as he is in the scope and play of the intellectual activities, the receptivity, the acquisitiveness, the retentiveness, how experience is rationalized, and how constructively it has been used. This searching examination sometimes reveals strange things. Many individuals are found to shade off below the lower range limit of what we term normal into the neurasthenoid, the hysteroid, and the psychasthenic without any previous recognition of it, because favored by circumstances or undiagnosed.

All this detailed probing aims to measure the degree of the candidate's nervous stability, to find how his emotional system will stand up in the moment of supreme test when his life depends on it, and our authority quotes Dr. R. F. Longacre, a distinguished medical expert of aviation, as saying that "a moment of time must serve in emergency at speeds upward of two hundred miles per hour in an unstable medium, with fatality as the penalty of error or delay."

When we trust our lives to the steady-eyed young pilot in his natty uniform and

nonchalant air, as if he has not a care in the world, it is reassuring to know that he has gone through this searching test, reaching into every nook and cranny of his being, and that he has come through it with a clean bill of physical, mental, nervous, and spiritual health. If similar tests were applied to automobile drivers, it is fairly safe to say that we would not have our present death roll of 30,000 fatalities a year.

Spending \$3,848 to Find One Disease Carrier

Is that amount too much? Is this an example of the high cost of government that is piling our taxes mountain-high and making us all work like slaves to support an army of job holders? Well, let us see. This rather expensive disease carrier was located in 1929, it appears, by the Connecticut State Department of Health in its examinations of the food handlers, and was the only one detected that year. That was what made his cost so high. In 1931, 27 carriers were found, at a cost of \$387 each, which was cheaper, but we would probably prefer one at \$3,848 to 27 at \$387 each. It would indicate a better state of affairs in the handling of our food supply.

Our grandfathers did not have to pay any taxes that were spent for the detection of disease carriers who were handling their food. They merely had diphtheria, scarlet fever, septic sore throat, tuberculosis, typhoid and paratyphoid, etc., without inquiring very closely where they came from. Now we exercise a little more curiosity about it and, of course, curiosity costs money. But we figure that it is worth what it costs, and often much more besides. A survey in Massachusetts listed 21 milk handlers who were typhoid carriers and who had caused 426 cases, or an average of 20.3 cases each. That money was certainly well spent.

An instructive presentation of the cost of detecting disease carriers, as contrasted with the cost of not detecting them, is given by several experts of the Connecticut Department of Health in a paper read before the American Public Health Association. In Connecticut, it seems, the handlers of certified, Grade-A raw and

pasteurized milk are subjected to periodical health examinations, while the handlers of ungraded raw milk are not. The ungraded raw milk forms 42.2 per cent of the total supply so that that percentage is unprotected from disease carriers. If we say that the unguarded 42.2 per cent is consumed by 42.2 per cent of the State's population, and the protected 57.8 per cent is consumed by 57.8 per cent of the population, which seems a reasonable way to reckon it, then 708,389 Connecticut consumers are unprotected, and 970,258 are protected, by the inspection of the milk handlers. If the State is undertaking at all to protect its people from disease carriers, it hardly seems logical to leave 700,000 of them in peril of the dangers from which the rest are guarded.

The cost, too, is little enough when we come to figure it out on a per capita basis. The total cost of this service for last year was not over \$20,000. Distributing this among the 970,258 persons who were protected by it, it comes to less than 2 cents a year for each consumer, certainly not an extravagant figure. Or if we reckon it on the basis of the quantity of milk safeguarded, it is less than 12 cents for each 1,000 quarts.

Has the inspection actually proved itself to be worth the cost? The answer to that is that no outbreaks of milk-borne diseases have occurred among users of the certified, Grade-A raw or pasteurized milk since the inception of milk handler control. On the other hand, there have been seven such outbreaks attributed to the unguarded raw milk during the 77 months covered by this study: 4 of scarlet fever and septic sore throat, 2 of typhoid fever, and 1 of paratyphoid fever. The outbreaks of scarlet fever and septic sore throat involved 328 cases, with 5 deaths, and the outbreaks of typhoid and paratyphoid fever involved 55 cases, with two deaths. Taking 3 weeks as the average time of illness for the first group and 8 weeks for the second, we have the amazing total of 1,424 weeks, or over 27 years, during which persons were forced to remain away from business, school, or home duties because of illness due to milk infected by carriers. Add to this the cost of medical care for the 383 patients, the

economic loss of 7 lives, and the cost of 7 funerals, and ask if it does not far outweigh what it would have cost to guard the milk supply which caused all this waste and wreckage.

While our costs of government are piling and pyramiding higher and higher, let us stop and examine some of our expenditures and see if it would not pay in cold cash to transfer part of them from useless frills and fol-de-rôls to work like this that makes us a stronger and healthier people.

As the Twig Is Bent

So, we are assured by the old saying, the tree's inclined. And on that principle the County Medical Society and the County Parent-Teacher Association of Westchester County are planning to bend the little twigs of New Rochelle in the direction of good health, in the hope that they will stay inclined that way when they grow older. For the idea behind this particular movement is that it shall not be just another child-health effort, but shall be the start of a continuous life-long health program, to be carried on as completely as possible under the guidance of the family physician acting as health counsellor.

It is to begin with a health examination of all children between the ages of two and five, but here again we have a new feature, for they are to be divided into three classes. First, all the mothers who can afford to do so are to be urged to take the children to their family physicians for examination in their private offices. Next, for those who cannot afford this, special pay clinics will be provided, at a fee of \$2.00, conducted in their own offices by physicians specially selected by the local Medical Society. Finally, the children of the indigent will be examined at the free clinics of the Baby Welfare Stations, largely by the same doctors who conduct the pay clinics. All three classes of examinations will be thorough and painstaking, but the first class will include procedures which cannot be given in a free or \$2.00 examination. All examinations will include a tuberculin test, if the parent will consent, a feature suggested by the Westchester Tuberculosis and Public Health Association.

If this plan is successful in New Rochelle, it will be recommended for adoption in the rest of Westchester County. It may well be watched by other counties, also, and emulated if it works out satisfactorily. The pre-school examination idea has become very popular throughout the country. Parent-teacher associations are strongly in favor of it. Too often, however, the children have been simply rounded up en masse and examined wholesale at special free clinics. As a result, the examinations have often been more or less sketchy, and the parents have been habituated to the idea that medical care is free. The Westchester plan is more far-seeing. It starts the little feet on a highway of health that will lead to a longer and stronger life, and teaches the family that real health service is worth saving for and paying for, and is worth all it costs in the end. It is a lesson the whole country needs to learn.

The "Team Doctor"

He will not make a fortune out of it, but he will have the time of his life, he will form lasting friendships with as fine a lot of young fellows as ever breathed, and he will save some of them from injuries that might mar their future usefulness and happiness. He probably is himself a former school or college athlete; he has felt the snap of a bone when the opposing team piled on top of him; he knows the agony that follows a kick in the stomach; he knows the danger of violent exercise when a lung or kidney has a tender spot or when the heart has a disturbing murmur or flutter. At the same time he wants his boys to win, and when Bill gets his wind after that kick below the belt he pats him on the back, sends him into the line again, and whispers to him to break through for a touchdown. At another time he has the courage to defy the coach and antagonize half the school or college by ruling out of the game a star performer who has a physical defect that will not stand the strain of rough play. In short, he must have the qualities that would spell success in any walk of life, yet accept the lean pay of the "team doctor." Impossible? Perhaps, but lots of fine men are doing it.

It is only in the last three or four decades

that the team doctor has come into the picture. Before that the coach used to dress cuts, bind up sprains, and even set broken bones. Mr. Parke Davis, it appears, used to be a coach, and tells of performing such services. "In my day," he says in a recent letter, "we coaches were also team physicians and surgeons." The athletes took their injuries as part of the game, and it was thought infantile to make any complaint, so nobody thought of asking for an attending physician to follow the team about.

The change to the better methods came with perfect naturalness, as Dr. Joseph E. Raycroft of Princeton University relates in an address before the American Student Health Association. Among the men graduated from medical schools in the '90's were some who had played on the teams in their school and college days. They saw the need, volunteered to look after the health of their old school teams in addition to their private practice, and led the movement to have regular team doctors provided. They also brought a fresh point of view. In previous years the aim had been only to make the athletes stronger and to develop their muscle. The new idea is to develop their health, too, and guard against disabling injuries. The skillful team physician can not only bind up an injury after it occurs, but he can devise special protective and preventive strapping, bandaging, and padding that will keep the injury from happening at all. With his own experience as an athlete he can tell his team members how to handle themselves to avoid injury in the rough-and-tumble of the game.

Much remains to be done in this field. True, the leading colleges and private schools have their team doctors, but very few of the thousands of high schools have anything of the sort. Yet the life and health of a high-school boy is just as valuable to himself, his parents, and the community as those of a college boy. When the list of football fatalities is published every year, the school teams supply most of the names, and the reason for it is that they have little or no expert supervision. It is greatly needed, and the local physicians have a door of opportunity standing open before them here to help the young chaps who will be our men of tomorrow.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Patient and Physician—Waiver of Privileged Communication

As has been stated from time to time in these columns, the law of this State forbids a physician from revealing information concerning his patients which he obtained in attending them in a professional capacity. This has been the general rule ever since the Legislature over a hundred years ago enacted a statute covering the subject. The law has been continuously in effect ever since, and at present is incorporated into the Civil Practice Act, as follows:

"Sec. 352. *Physicians and Nurses Not to Disclose Professional Information.* A person duly authorized to practice physic or surgery, or a professional or registered nurse, shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary to enable him to act in that capacity, unless, where the patient is a child under the age of sixteen, the information so acquired indicates that the patient has been the victim or subject of a crime, in which case the physician or nurses may be required to testify fully in relation thereto upon any examination, trial or other proceeding in which the commission of such crime is a subject of inquiry."

From time to time the Courts have established exceptions to the rigor of the said rule. For example, it has been established that in a malpractice action the patient is not entitled to invoke the rule to prevent the defendant doctor from calling witnesses to testify as to the physical condition of the patient. Very recently the Court of Appeals made an important decision in which it determined that under certain other circumstances a patient was not entitled to invoke the rule.

In the years 1928 and 1929, a certain J. made four written applications for life insurance policies. Before the policies were issued he was examined by the company's doctor. Certain questions were asked of him in the course of the examination and his signed answers thereto were attached to and made part of the policies that were issued. Included in the questions put to him and the answers which he gave were the following:

"Have you ever consulted a physician or practitioner for or suffered any ailment or disease of * * * the heart, blood vessels or lungs? No."

"Have you ever consulted a physician or practitioner for any ailment or disease not included in your above answers? No."

He also gave the answer that the only doctor who had examined or treated him within the past five years had been a certain doctor who had treated him for a cold, and that he was well in a few days.

In 1930, the assured became afflicted with an active pulmonary tuberculosis. He notified the company and was examined by its physician, after which he received payments under the disability benefits provided for in the policies in an aggregate amount of \$2,000 over a period of nearly a year. During that time under the terms of the policies, no premiums were paid by the assured. The company then discontinued making payments of disability benefits to J. and notified him that it would cancel the policies unless he paid the premiums that had been waived during the period of disability.

The assured thereafter brought an action against the company to require it to continue to pay him disability benefits and to restrain the company from canceling the policies. The answer which the company put in in the action admitted that the policies had been issued, and that it had refused to pay disability benefits, but set up as a special defense, the charge that the assured had been induced to issue the policies by fraud. The company alleged that the plaintiff had failed to disclose that prior to the date he applied for the insurance, he had suffered from pulmonary tuberculosis.

The case came on for trial and the plaintiff put the policies in evidence and called as a medical witness a doctor who had examined him for the first time the day before the trial. That physician testified that the plaintiff was then suffering from moderately advanced active pulmonary tuberculosis. He stated that in his opinion the same condition had existed for seven months before the trial and that the plaintiff was totally disabled by reason of the disease.

The defendant insurance company produced as witnesses two physicians. Each testified that they were acquainted with J. The first testified that the plaintiff had consulted him professionally about half a dozen times prior to December, 1928. The other testified that he had seen the plaintiff

a few times before that date. The defendant's counsel asked each of the doctors the question: "At that time did you find him suffering from any ailment or disease?" This was objected to on the ground that it was a privileged communication, and that the plaintiff was entitled to keep the doctors from testifying by reason of section 352 of the Civil Practice Act. After conference with the Court the question was withdrawn and again asked in the following form: "At the time he consulted you, or on the occasions he consulted you, was he suffering from any ailments or disease?" An answer to the effect that the plaintiff was sick was permitted. The next question was: "What was that ailment or disease, doctor?" And as to that question the Court ruled that it could not be answered because of the prohibition contained in section 352.

The trial terminated in favor of the plaintiff, and an appeal was taken. The Appellate Division by a divided Court affirmed the judgment of the Trial Court below, but the case was carried up to the Court of Appeals, the highest Court of the State. The said Court directed a reversal of the judgment, and ordered a new trial ruling that under the circumstances the doctors should have been permitted to give their testimony.

The Court upon determining the matter stated its interpretation of the purpose of the statute as follows:

"In considering the application of the section under the facts of this case, the purpose of the statute and the public policy evidenced by the enactment should be appreciated. Its purpose is to protect those who are required to consult physicians from the disclosure of secrets imparted to them; to protect the relationship of patient and physician and to prevent physicians from disclosing information which might result in humiliation, embarrassment or disgrace to patients. When the original statute was enacted, it was believed that the benefits which would accrue from its enactment by preventing disclosure by patients of information gained in consultation and by inspiring confidence between patients and their physicians would outweigh any injustice which might result in particular cases caused by the exclusion of testimony by physicians at trials."

The Court summarized its reasons for its decision as follows:

"When the respondent called a physician as a witness who testified that for at least seven months the respondent had been suffering from 'active pulmonary tuberculosis,' he exposed his condition to the public and disclosed the secret which the statute was enacted to protect and keep secret. By his own act he removed the pro-

hibition of the statute and waived upon the trial the protection which it afforded him.

"The contention that a patient may waive the privilege afforded by the statute himself by calling a physician and disclosing his physical condition and at the same time insist that the statute bars the defendant from calling a physician to describe his physical condition, if sustained, would in many cases result in injustice and fraud. It would be making a use of the statute never intended by the Legislature and not now approved by this Court. It is urged by respondent that even if it was proper to permit testimony to be given by the doctors called by the defendant as to respondent's physical condition during the seven months preceding the trial referred to in the testimony given by the doctor called by respondent, it would not have been proper to allow testimony by them as to his condition over three years before that time when the applications for insurance were signed.

"Such contention overlooks or ignores the purpose of the statute.

"There would be no more humiliation, mortification or disgrace in having the fact disclosed that he was suffering from pulmonary tuberculosis over three years and seven months before the trial than in the fact that he had that disease for seven months before the trial.

"If his condition could not be shown as it existed three years before, could it be shown as it existed three months or three weeks before?

"The disease is a progressive one. Respondent may or may not have suffered from it at the time he signed the applications for insurance. That was the issue in the case, and in fairness to the appellant, it was entitled to have received the testimony of doctors who examined him before the application was signed."

The decision is unquestionably a just one. As the Court pointed out, the plaintiff through his own witnesses disclosed to the world his own physical condition, and thus it would be manifestly unfair for him to seek to seal the lips of the physicians called by the defendant who could testify to facts that were material to the issue.

Death from Peritonitis

A surgeon was called in consultation by a general practitioner in connection with the treatment of a woman 38 years of age. He received a history that the patient had been suffering a few days from severe lower abdominal pains which had become persistently worse. An examination showed marked tenderness and rigidity of the entire lower abdomen with considerable distention. A vaginal examination showed marked tenderness behind the uterus and a sensitive mass in the pelvis behind the uterus and there was severe pain in attempting to move the cervix. A diagnosis was made of pelvic peritonitis and the patient was immediately removed to a

hospital for treatment. The patient was given hot irrigations and the next day she showed considerable improvement, her temperature having gone down to normal and her pain having almost entirely disappeared. The day thereafter, however, her general condition grew rapidly worse with severe abdominal pains, together with nausea and vomiting.

Another surgeon was called in consultation and he diagnosed her condition as one of intestinal obstruction due to postoperative adhesions following the previous operation. Both surgeons agreed that an operation was necessary and one was immediately performed. The first surgeon opened the abdominal cavity, found it to contain a large amount of thin odorless purulent fluid. The appendix was found to be swollen, bright red in color, but not perforated. The culture taken from the abdominal fluid indicated that there was a hemolytic streptococcus infection present. The postoperative diagnosis was that of general peritonitis and acute appendicitis. Following the operation, the patient failed to rally and died the following evening.

An administrator was appointed who instituted an action to recover damages charging the defendant with having caused the death of the decedent, based upon the claim that he failed to properly observe the patient's symptoms to operate upon her soon enough to save her life.

The case came on for trial and the issues of the case were submitted to a jury which rendered a verdict in favor of the defendant, thereby exonerating him from the plaintiff's claim that he had been guilty of malpractice.

Treatment of Lacerated Hand at Clinic

A man 28 years of age entered a hospital clinic for treatment of a lacerated wound from the palmar surface of his hand. He stated that he had cut his hand by falling on some broken glass. He was treated in the emergency ward by an interne who clamped and tied off the bleeding blood vessels and inserted five sutures and a drain. It was found that the tendon was severed, but it was not sutured because of the hemorrhage.

The following day he returned to the clinic and was there seen by the surgeon in charge who shortened the drain and redressed the hand. He never saw the patient thereafter.

An action was brought against the surgeon charging him with malpractice and claiming that in treating the patient he had broken a needle which he had allowed to remain in the patient's hand. He claimed that he had been obliged to undergo an operation for the removal of said needle. The surgeon had no recollection of the matter at all, the patient having been treated as one of the routine clinical cases and so far as he was able to ascertain from the hospital records of the case, he had never used any needle in treating the patient.

An examination before trial was had of the defendant, and he testified that he had used no needle in connection with the case and that so far as he knew no needle had been broken by anyone in the treatment of the case at the clinic. After the said examination before trial the plaintiff's attorney stipulated to discontinue the action against the surgeon.

LIVING WITH HALF A BRAIN

The mystery of how and why we think, live, move, and have our being deepens as we learn that patients not only survive with half the brain taken out but read, write and figure and are free from mental disorders. Dr. Walter E. Dandy, of the Johns Hopkins Hospital, reports that he removed the entire right cerebral hemisphere of three patients without disturbances of the thought processes of any one of them. It was "most disappointing" to him, he says in his report to find "that some functions of the brain are not stored or at least are not activated there." These disclosures are intensely interesting and observes the Virginia Medical Monthly, and it adds that, although familiar with the experiments upon decerebrated frogs and pigeons and with the behavior of Goltz's dogs it is difficult for us to

realize that the human being can survive the loss of an entire cerebral hemisphere. To be told that he can survive it without demonstrable mental defect is even more astonishing. Post-operatively all of Dandy's cases showed hemiplegia and hemianesthesia but he reports that they were perfectly oriented and memory was unimpaired that they were able to write, read, and handle figures accurately that they were coherent and free from abnormal mental states such as phobias, delusions, hallucinations, melancholia, and expansive ideas. The fact that none of these patients survived operation many months may be important in the mortality statistics of neurological surgery but this minimizes in no way the interest Dr. Dandy's paper has for the student of the physiology of the brain.

Books

BOOKS RECEIVED

[Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.]

The Harvey Lectures.—Delivered Under the Auspices of the Harvey Society of New York, 1932-1933. Series 28. Julius Bauer, M.D., L. O. Kunkel, M.D., and others. Octavo of 233 pages, illustrated. Baltimore, Williams & Wilkins Company, 1934. Cloth, \$4.00.

The Study of Anatomy.—Written for the Medical Student. By S. E. Whinnall, M.D. Second Edition. 12mo. of 93 pages. Baltimore, William Wood & Company, 1933. Cloth, \$1.50.

Contagious Diseases.—What They Are and how to Deal with Them. By W. W. Bauer, M.D. 12mo. of 218 pages. New York, Alfred A. Knopf, 1934. Cloth, \$2.00.

Nature, M.D.—Healing Forces of Heat, Water, Light, Electricity and Exercise. By Richard Kovacs, M.D. 12mo. of 181 pages, illustrated. New York, D. Appleton-Century Company, 1934. Cloth, \$2.00.

The Practical Medicine Series.—Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Series 1933, Chicago, The Year Book Publishers [c. 1933]. The 1933 Year Book of Pediatrics, edited by Isaac A. Abt, M.D., and Arthur F. Adt, M.D. 12mo. of 548 pages, illustrated. Cloth, \$2.25.

International Clinics.—A Quarterly of Illustrated Clinical Lectures and Especially Prepared Original Articles on Treatment, Medicine, Surgery, etc. Vol. 1, 44th Series, 1934. Louis Hamman, M.D., Editor. Octavo of 320 pages, illustrated. Philadelphia, J. B. Lippincott Company [c. 1934]. Cloth, \$3.00.

Surgical Clinics of North America.—Vol. 14, No. 1, February, 1934. (Philadelphia Number.) Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinic Year (6 issues) Cloth, \$16.00; Paper, \$12.00.

Demonstrations of Physical Signs in Clinical Surgery.—By Hamilton Bailey, F.R.C.S. Fourth Edition. Octavo of 287 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$6.50.

An Outline of Immunity.—By W. W. C. Topley, M.D. Octavo of 415 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$6.00.

Aids to Neurology.—By E. A. Blake Pritchard, M.D. 16mo. of 376 pages, illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$2.00.

Bergey's Manual of Determinative Bacteriology.—By David H. Bergey, Fourth Edition. Octavo of 664 pages. Baltimore, The Williams & Wilkins Company, 1934. Cloth, \$6.00.

Practical Methods in Biochemistry.—By Frederick C. Koch, Octavo of 282 pages, illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$2.25.

Recent Advances in Psychiatry.—By Henry Devine, M.D. Second Edition. Octavo of 364 pages. Philadelphia, P. Blakiston's Son & Co., 1933. Cloth, \$4.00.

Practical Medicine Series.—Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Series, 1933, Chicago, The Year Book Publishers [c. 1933]. The 1933 Year Book of Dermatology and Syphilology. Edited by Fred Wise, M.D., and Marion B. Sulzberger, M.D. 12 mo. of 458 pages, illustrated. Cloth, \$2.25.

Practical Medicine Series.—Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Series 1933, Chicago. The 1933 Year Book of Neurology and Psychiatry. Neurology, edited by Peter Bassoe, M.D. Psychiatry, edited by Franklin G. Ebaugh, M.D. 12 mo. of 470 pages, illustrated. Cloth, \$2.25.

BOOKS REVIEWED

Human Sex Anatomy.—By Robert Latou Dickinson, M.D. Quarto of 320 pages, illustrated. Baltimore, Williams & Wilkins Company, 1933. Cloth, \$10.00.

This book is one of several sponsored by the National Committee of Maternal Health Inc. Because of the need for exact anatomy as a basis for the thorough understanding of sex physiology, it was thought necessary to start at the beginning and collate published material, and also to issue hitherto unpublished data on sex anatomy of humans.

The drawings are wonderfully well done. The author says that much of the value of the volume is in the anatomical illustrations. The reviewer is of the opinion that the description of sex anatomy and physiology given in the text is excellent and sufficient. The book would be in better taste if a few of the illustrations had not been published.

WM. SIDNEY SMITH

Modern Clinical Psychiatry.—By Arthur P. Noyes, M.D. Octavo of 485 pages. Philadelphia, W. B. Saunders Company, 1933. Cloth, \$4.50.

The author has had great experience in the field of acute and chronic psychiatric disorders. His book is written in the light of his own rich experience. However, it gives due consideration to the opinions of others, and throughout the text there are references to the publications and theories of the various workers in different fields of psychiatry. It differs from many books in the respect that it is written in a facile pen and holds the attention of the reader throughout.

This book is highly recommended because of its thoroughness, the method of presentation of its contents, and the remarkable way in which it holds the attention of the reader. It should serve as a model text book for medical students.

IRVING J. SANDS

Neurology.—By Roy R. Grinker, M.D. Octavo of 979 pages, illustrated. Springfield, Ill., Charles C. Thomas [c. 1934]. Cloth, \$8.50.

Here is the modern version of a system of neurology.

This volume possesses fundamental and reliable explanations of all the facts in a readable and understandable manner. This is a book which can well serve to bring any physician up to date in an important field of medicine without losing himself in a forest of esoteric technicalities. For the student it is of equal importance because it offers a clear elucidation of the newer biological concepts as applied to neurology while serving as a thorough-going text book. It is thus that a biological analysis of each group is developed as an introduction to the study of the anatomy, histology, physiology, and pathology of the various chapters in neurology.

SAM PARKER

Red Medicine: Socialized Health in Soviet Russia.—By Sir Arthur Newsholme, M.D., and John A. Kingsbury, LL.D. Octavo of 324 pages, illustrated. Garden City, N. Y., Doubleday, Doran & Company, 1933. Cloth, \$2.50.

A very good title for a book describing the care of the sick to-day in Russia.

The authors endeavor to appraise the prevailing system of medical practice as observed by them on a special mission to Russia for this specific purpose. They stress their attempt to present the situation in an unbiased manner. The authors, however, are well-known advocates of state medicine, or at least, of systems bordering very closely upon it. It is our impression that the defects in the Russian system have been overlooked in this volume.

The book should be read by every wide-awake physician. In these days, when the advocates of state medicine are very active, it behooves the medical profession to be well informed as to the arguments for and against socialized medicine.

Merely to use obstructive tactics will not suffice. Changes in some of the present methods of private practice are coming. The medical profession must be prepared to lead and guide in these changes. Constructive thinking and action are required; otherwise, nonmedical health leaders will do it for us.

A. E. SHIPLEY

REMARKS OF THE INCOMING PRESIDENT
ACKNOWLEDGING HIS INTRODUCTION

ARTHUR J. BEDELL, M.D.

*Albany**Mr. President, Ladies and Gentlemen:*

In assuming the duties of the President of the Medical Society of the State of New York, I am deeply conscious of the honor conferred upon me and well aware of the numerous weighty decisions that will have to be made this year.

My predecessors in this high office have all devoted their energies to the improvement of the practice of medicine in bad times as well as good, to the end that the people of the State of New York have never been as healthy as to-day.

The period of general economic stress continues in spite of many experimental methods of stimulation directed toward its relief. We believe it is our right and indeed our bounden duty of the present to look to the future after serious contemplation, and ask where we as American people are going. I believe that we should be informed regarding the road as well as the destination. As men and women engaged in one of the highest callings, we have by training and contact become versed in the reactions of the human body and mind. We would be negligent in our trust if at this time we failed to direct medical thought into channels from which therapeutic inspiration, medical relief, disease prevention, and cure can be most readily acquired.

There is much talk about service rendered without profit. Surely there can be no lasting results in any field of endeavor unless they are based on economic satisfaction. You ladies and gentlemen will

return home to the practice of the profession into which you entered after an unusually prolonged, strenuous, expensive, self-sacrificing period of preparation. Don't be misled by the satans of propaganda who wish to take you on a high hill and offer you all that is visible so that they may from that time control not only your body but your very soul. Resist with all that is within you the beguilements of those who would ensnare you.

My felicitations are extended to the members of the Women's Auxiliary of the Medical Society of the State of New York. For many years I have spoken in favor of having a women's auxiliary in our State. Mrs. John O. McReynolds, a former President of the National Auxiliary, tried very hard to establish this unit, and I know that to-day she will rejoice with you in the consummation of one of her great desires.

We look forward to a close partnership and enlist your aid in preserving the dignity and the individuality of the practice of medicine. We know that you appreciate the trials, tribulations and satisfactions of the medical life and we are convinced that you will do all in your power to maintain the greatest efficiency of the physician, that you will prevent the implantation of false doctrines and strive to retain the good in our present system of medical service.

And now, Mr. President, with the help and counsel of all the members of this Society and the newly formed auxiliary, we look forward to a year of intelligent, cooperative, and well-directed activities.

Delivered at the Annual Banquet at Utica, N. Y., March 15, 1934

QUALIFIED MEDICOLEGAL EXPERTS, THEIR VALUE TO THE COMMUNITY AND TO THE MEDICAL AND LEGAL PROFESSIONS

CHARLES NORRIS, M.D.

New York City

In the past this matter has been neglected. This neglect is traceable and involved in the evolution of medicine in our country. In the early days the physician served an apprenticeship with a physician or surgeon, and thus he slowly learned his medicine. Then there was a period of medical schools almost entirely proprietary in character, followed by a period in which the splendid medical schools have been slowly evolved. Scientific research and all phases of medicine have made marvelous strides. However, medicolegal medicine has not established itself anywhere in this country on a firm and progressive basis. The reasons for this neglect will be taken up later in the discussion of the second division of my subject, namely, the legal or official status of the coroners and medical examiners' systems of the country. Let me briefly state my conception of the qualifications of a medical examiner. The primary qualification is that he must be thoroughly versed in the practical side of pathology, hence a long and varied autopsy experience. The pathologist who has had varied experience in hospital work of this character is, in my opinion, qualified to begin his task along medicolegal lines. He will, however, run across cases in which he will be puzzled, since his experience has not included just that kind of a case. "One of the most interesting of the problems encountered daily is that even after a thorough post-mortem examination we may be in doubt as to the cause of death." To elucidate, when an unknown adult is found in coma, and there is no history connected with the death, and no previous medical history is available, frequently nothing is found which will indicate to an experienced pathologist the cause of death. Thorough follow-up work is required. In a large city, most of these cases fall into the group of narcotic, alcoholic, ethyl or methyl, and various other poisons, including overdoses from barbituric acid compounds, strychnine and very acute cases of sepsis.

After autopsy, the subsequent work entails chemical, microscopic, and bacteriologic examination of the viscera, and in homicidal cases examination of suspected blood stains to determine if they are actu-

ally blood, and if blood, whether of human or animal origin and the examination of seminal stains. Serological examinations may be necessary, involving the use of the precipitin reaction, and blood-grouping tests which may help in the identification of the person.

A little consideration will convince the reader that no one man is competent or able to perform alone all of these tasks. However, the head of a department, the medical examiner of a county or of a city, should have enough experience to realize the importance of the work at hand, sufficient knowledge to see that there is preserved enough tissue for chemical and microscopic examination. A prevalent belief is that all that is necessary for toxicological analysis are the stomach contents. Chemical tests on this material are important, of course, but alone do not afford opportunity for making valuable observations and deductions which are necessary to elucidate a case of poisoning. Until absorption takes place from the stomach, the contents of the latter may be considered to be outside of the body. It is, therefore, of extreme importance to accurately determine qualitatively and quantitatively, the amount of poison in the brain, liver, kidneys, and other organs where the poison may be deposited as in the bones in radium and lead poisoning.

Success of any toxicological investigation depends upon the intelligence and foresight of the pathologist or medical examiner making the autopsy. The decision as to whether a chemical analysis should be carried out rests with him. In cases of poisoning there is a tendency to overestimate the work of the toxicologist or perhaps underestimate the work of the pathologist performing the autopsy.

The term forensic medicine denotes all in medicine that may be applied in law and all in law that has to do with medicine. The terms legal medicine, medical jurisprudence, and forensic medicine are generally used synonymously, although they are not. Legal medicine means, strictly speaking, medicine which is legal as differentiating it from medicine which is illegal, and using it in the accepted meaning, medicine

as applied to legal cases. Medical jurisprudence refers to jurisprudence as applied to medicine. Forensic medicine has reference to the use of medical science to elucidate legal problems. I have quoted from that splendid volume of Alfred W. Herzog, entitled "Medical Jurisprudence."

A symposium upon the interesting and important subject of medicolegal investigation is of striking significance as forensic medicine has been notoriously neglected in this country. It is properly handled in Suffolk County, Mass., the City of Boston, New York City, and Newark, N. J. In these three cities the coroner's system has been overthrown and the medical examiner's system has been installed.

Specialism in medicine and surgery have grown enormously, and I do not hesitate to state that coroner's physicians, autopsy surgeons, or medical examiners, to be thoroughly competent, must be specialists who devote their entire time to this important subdivision of medicine.

That part of forensic medicine which concerns itself with the accurate determination of the cause of death, readily divides itself into two divisions. The first, and certainly for the medical profession the most important division, is that which concerns itself with the cause of death, a strictly medical problem.

The undergraduate and graduate students are given almost no medicolegal training in our medical schools. In my opinion, this is responsible for the unfamiliarity of physicians and surgeons with their obligations to the coroners or to the medical examiners, *i. e.*, to the prosecuting arms of the law, the police, and the district attorney.

There is a curious misconception and failure to understand what constitutes a medical examiner's case. From time immemorial the State has assigned to a certain group of physicians the responsibility for determining the cause of death.

I quote from Dr. Oscar T. Schultz:

A dead body is found. What a host of questions must be answered! Whose corpse is it? How came he to his death? By natural causes by accident, suicide or murder? Is anyone criminally responsible? Efficient, painstaking prompt investigation by experts is required. If someone is criminally responsible society demands that he be promptly apprehended and properly dealt with. The first inquiry can be handled only by experts in medical and allied sciences. The skilled pathologist aided by the immunologist, the chemist, the toxicologist and the bacteriologist must answer as to the physical cause of death. Then the experts in investigation and detection of crime with skilled technicians in photography, fingerprint reading, identification of individuals and such matters, must discover and

apprehend the perpetrator, after which the prosecuting officers and courts must function.

The evidences with which the medical experts must deal with will usually be found upon or in the body, the most important of those which the other investigators must handle will usually be found in or on the body and on or about the scene of its discovery. How tremendously important it is, then, that the investigation be made immediately, and before the body or place has been in the slightest disturbed? And how important it must be that skilled persons with adequate equipment be instantly available. European cities have realized this and have made most thorough preparation in personnel and equipment for criminal investigation. In most places in this country the initial investigation is made by the coroner.

How competently this work is done should be a matter of concern to every community, and of especial concern to thickly populated urban centers where crime and its detection and punishment assume great importance. That duties which fall upon the coroner are not always performed in a thoroughly competent and scientific manner must be apparent to everyone who has given any thought to the subject. The generally unsatisfactory character of the work of the American coroner is reflected in the backward state of medicolegal science or forensic medicine in the United States.*

CASES INVESTIGATED BY THE EXAMINER

The kinds of cases to be referred to the medical examiner are specified in the following section, in which it is important to note that the police are required to notify directly the office of the medical examiner.

When in the city of New York, any person shall die from criminal violence, or by a casualty, or by suicide, or suddenly when in apparent health, or when unattended by a physician, or in prison or in any suspicious or unusual manner, the officer in charge of the station house in the police precinct in which such person died shall immediately notify the office of the Chief Medical Examiner of the known facts concerning the time, place, manner, and circumstances of such death.

Dr. W. J. MacNeal describes the functions of the medical examiner in these words:

The functions of the office of chief medical examiner are exclusively concerned with investigation and adequate record of scientific facts. The policy of this investigatory office is according to the chief examiner to bring out all facts, medical, pathological or chemical, and to present such evidence in proper fashion that is to make direct and trustworthy inferences. Any failure or neglect of this cardinal rule destroys at once the independent standing of the office and would tend to impair its prestige as an unbiased scientific agency. The detective and legal investigations formerly in the province of the coroner are turned

* Quotation from "The Coroner and Medical Examiner" by Oscar T. Schultz and E. M. Morgan published by the National Research Council, National Academy of Science, Washington, D. C., Bulletin No. 64.

over by law to the police and to the district attorneys, who proceed with their work on the information and findings furnished by the medical examiner. Inquests such as were held by the coroner are no longer made; the judicial functions are now held before the magistrates in the Homicide Courts and by the grand jury under guidance of the district attorney or before a referee in compensation cases. To aid in his investigation, the medical examiner has been given the power to administer oaths, take affidavits, proofs, and examinations as to any matter within the jurisdiction of the office. He has practically summary powers and acts freely in his own field without interference from police or district attorney. He also has power to summon witnesses to his office. The determination of the cause of death is primarily a medical problem in all cases. In most cases of violent or suspicious or mysterious death, it is a problem which lies strictly within the province of the medicolegal pathologist. It is essential and right that the office of chief medical examiner should be allowed freedom of action in the investigation of these cases. The law requires that the medical examiner, being notified of the death, shall 'go to the dead body and take charge of the same.' No one may move a dead body without his consent or remove objects from a room where a death occurred in such cases. With the exception that the police may take charge of valuables the medical examiner controls everything relating to such cases until his examination has been completed. The law is carefully worded to give the medical examiner control of the dead body under investigation and leaves to his discretion the matter of an autopsy. It also emphasizes that the report of each case shall be promptly rendered to the district attorney whenever, in the judgment of the medical examiner in charge, there is any indication of criminality."

A medical examiner should have the qualifications of a well-trained and cultured pathologist, and he should be given the facilities to make bacteriological, microscopical and chemical studies. It is an impossible task to make use of the volume of material along these lines as successfully as one would wish. The routine work performed by the chemical department is enormous. Dr. Gettler, who is the toxicologist, has most unusual experience and training. He should be provided with well-trained assistants, with a salary enabling them to live independently from other sources of income. The "research work" is a necessity in many of our cases. Many years ago Dr. Gettler and Prof. Haines of Chicago, spent five to six months examining the viscera of a celebrated case at the chemical department of Bellevue Hospital. Extraordinary problems are encountered in many of the routine investigations.

I am enthusiastic to tell of the needs of the office, the glaring deficiencies. The microscopic section work is considerably hampered by the lack of trained technicians. At the present time there is only

one worker who cuts the sections for us in the cases in which it is absolutely necessary for us to inform ourselves concerning the microscopical appearances in order to determine the kind of disease processes which are present.

Attention is called to the signal lack of medicolegal training furnished to undergraduates and graduate students by the medical schools, and this is responsible for the marked unfamiliarity of physicians and surgeons with their obligations to coroners or medical examiners, which means to the prosecuting arms of the law, the police, and the district attorney. How many times have bullets abstracted at operations or removed from the clothes, been lost or misplaced and thus have remained unidentified. Clothes are in many instances thrown away. They are often of the greatest value in court cases. On the other hand, descriptions of wounds, if powder-marked or smudged, are not noted on the surgical histories. One can realize how important these markings are, especially in homicide cases where a defense of suicide is maintained and where death intervenes hours later. The patient has always been washed and then the determination by the medical examiner on this important point, namely, the distance that the gun was held, is impossible. The value of the evidence furnished by the hospital or private physician may be, therefore, of vast importance.

At Bellevue I have preached to the hospital internes the desirability of withdrawing blood from patients suffering from carbon monoxide poisoning. In most cases the simple dilution test is all that is necessary; it can be done in the course of a few minutes and it is always successful where the percentage of carbon monoxide is 10 per cent or more. After twenty-four hours, it is difficult, except by the Van Slyke method, to determine the presence of smaller percentages of carbon monoxide. In a similar way, in cases in which overdosage of drugs or poisons or accident or suicide plays a rôle, efforts should be made to preserve the vomitus and the urine. These specimens must be religiously kept and sent to the chemical laboratory to determine the presence of the metals or alkaloids, etc., whether such patients die or recover.

The mutual relationship of the practitioner to the medical examiner or coroner's physician is an intimate one, and I may say closer cooperation must be established before success in the elucidation of many death cases will be forthcoming.

Industrial compensation cases need a few minutes of exposition. All casualty cases come under the jurisdiction of the medical examiner. There is no definite time limit when this rule becomes obsolete. The casual finding of a bullet at autopsy, in a man who was shot in the Civil War I would not bring under the jurisdiction of the medical examiner. Where the deceased has been shot in the World War or even in the Spanish-American War, the situation is altered. It is the function of the medical examiner to render his opinion upon the cause and effect of the bullet wound in regard to the death of the deceased. Upon our judgment depends the adjudication of claims by the Veteran's Bureau, or in the cases of industrial accidents, before the compensation court. This is a duty which we cannot pass up, and it is a task not readily undertaken by the busy practitioner or the hospital attendant.

Accurate mortality statistics are based upon complete autopsies. Let me illustrate: A severe cardiac decompensation enters the hospital and dies before a satisfactory clinical examination is possible, and he is not autopsied. To illustrate again, a man entered the hospital and lived four days. A Widal reaction was weakly positive and the hospital history blank furnished to the medical examiner suggested a pneumonia and it was thus signed out by one of the medical examiners. Later typhoid bacilli were reported in the urine and stools. Our medical examiner's history and death certificate was then changed. On account of the volume of cases handled no autopsy was made on this case. It illustrates the necessity of postmortems where the clinical diagnosis is uncertain. The same may be said in many instances of glanders, anthrax, tetanus, hydrophobia, and encephalitis, when the examinations should include routine microscopic and bacteriologic examinations. Accurate statistics are thus made possible.

Sudden deaths, unless there is a reliable family history confirmed by a physician, require postmortem examinations, to eliminate suicide by cyanide, etc. Carbon monoxide deaths may be difficult of determination. A woman was apparently taken sick at about five o'clock in the afternoon, a doctor was called, she died an hour later and the doctor issued a certificate of heart disease. In an adjacent building some hours later a man was found dead and referred to the medical examiner who suspected gas, and learning that a woman next door had also died, he sent both bodies to the morgue. A large amount of carbon

monoxide was found in the blood of both, the gas coming from the defective flue of a water heater. Before the settling of the blood which occurs after death, the cherry-red discoloration of the dependent portions of the body may not be present. It is only later that this characteristic becomes pronounced and makes the diagnosis comparatively easy. Often the families remove bodies of their relatives from the place where the person had turned on the gas with suicidal intent, open all the windows and remove the body to some other room. If seen before the cherry-red discoloration is pronounced, it is difficult, with an evasive history, to make the diagnosis of gas poisoning. Again a man evidently suffering from anginal attacks, who was found in his bathroom, with the gas turned on and with his lips stained a peculiar reddish color. He had marked coronary sclerosis and fibrous myocarditis. But the cause of his death was illuminating gas poisoning, 58 per cent of carbon monoxide being present in his blood. Furthermore, the mercurochrome found in the stomach and the small gut, even to the ileocecal valve indicated that it had been swallowed hours before death. Attempts were made by the lawyer of the family to have us alter the death certificate, and several physicians maintained that the death was not due to illuminating gas poisoning. No person can live with 40 per cent of carbon monoxide in his blood unless he is removed at once from the gas-laden atmosphere and long-continued efforts at resuscitation are maintained until his recovery. Fifty per cent is a lethal percentage.

Fighting the suicide clause is a financial measure. We omit the "suicide" when we believe that there is not sufficient evidence to warrant this conclusion as the law advises us to err on this side. Certificates are often signed "undetermined" or "pending investigation."

Our functions are investigatory, and we are responsible not only to the family of the deceased but to the insurance companies, compensation and civil courts. Misinformation at times leads us astray. I recall one case with very disastrous results to the insurance company involving \$150,000. It was handled on tour and signed out. The body was then embalmed and on the day of the funeral a representative of an insurance company in which the deceased was insured asked me to stop the funeral and perform an autopsy. The autopsy indicated cyanide poisoning and not pneumonia. It was impossible to prove cyanide present because of the formalin.

No class of cases are so annoying and so unsatisfactory as criminal abortions. Unjust accusation of physicians and midwives must be guarded against, when one bears in mind the large number of spontaneous abortions among multiparae. Ascertainment of the number of criminal abortions performed daily in New York City is an intriguing subject, but no satisfactory answer to this query is possible. Under certain conditions an abortion is justifiable, even if nonlegal. It is unnecessary to enter into details. To recall the many brutal and inhuman criminal abortions that I have witnessed is revolting. A physician who performs a criminal abortion on a woman in his office who is in her third or fourth month of pregnancy, and dilates and cures, and orders her home, commits murder. If indictment and conviction cannot be obtained the perpetrators should be sued for criminal malpractice and debarred from practice. Every effort should be made to punish these inhuman rascals and disbar them from the noble ranks of physicians. An erring girl, a first misstep—one doubtless forced upon her—I believe has a right to demand decent protection and a chance for her life. The horrible examples of criminal abortion I have witnessed are revolting, testifying brilliantly to the crass failures of our criminal laws and of our civilization.

It may be wondered that I referred only indirectly to the title of my paper. It is, however, explanatory of what follows. What are the measures to be adopted to improve the administration of medicolegal procedure? The problems presented by a large city differ considerably from those of smaller cities, towns, and counties. The organization in a large city where volume has to be taken care of is more difficult, and yet the problems presented in small cities or counties are similar, and careful autopsy work must be performed by competent pathologists, and follow-up work along the lines indicated in chemistry, pathology, and bacteriology.

A number of years ago I suggested that in small counties a hospital pathologist and the health officer might assume the rôle of medicolegal expert. Although the suggestion is a workable one, there are immense difficulties since throughout the country the coroner's physicians are appointed largely through political influence. The politicians or rulers have no appreciation of the work involved and many of them do not consider the work necessary. Any progress or change suggested will be considered work of a reformer who is despised because he

upsets the status quo. As the reverent John MacInnis says, "One of the great menaces to real democracy is that political interests and activities are frequently left to selfish exploiters who look upon politics as an opportunity to advance their own interests and feather their own nests.

Let us contrast the system prevalent in this country with the Central European countries, Germany, and Austria, where for decades hereditary intelligence has prevailed and high standards have been enforced. The people recognize the necessity of a thorough investigation of crime and of disease. The investigators are state officers with university training and experience and are appointed by the university. Before appointment to an important post, they have served many years as full-time assistants of experience. The work is supervised closely by the court as to the form in which their reports are written and in smaller towns and cities where the reports are made by less well known experts they are subject to revision by superior experts appointed by the court to serve.

We have nothing comparable to the foreign institutes. A Department of Forensic Medicine was established in New York City last year, a praiseworthy effort on the part of New York University and the Bellevue Hospital Medical School to improve conditions. Unfortunately, meager funds prevent serious work. An animal plant with trained keepers, assistants versed in serology, bacteriology, enough section cutters and laboratory men to perform the necessary work in pathology and chemistry are still wanted. A plant of this character requires of its workers much time, and money is necessary.

In a large city the medical examiner and his assistants should be full-time men without any other interests. Under the existing circumstances, it is not possible to demand from medical examiners that they be full-time men because of the low salary paid to them, and with no increments. Then the dread hanging over them like the sword of Damocles that they may at any time be removed and thus placed in the position in the future of not being able to obtain a living by the practice of medicine.

In a discussion of forensic medicine it is well to bear in mind that the function of the coroner's physician, autopsy surgeon, or medical examiner is purely investigatory. The autopsy must be performed by thoroughly trained and competent microscopists, in a laboratory, capable of running through and sectioning tissues for examination. Also a competent chemist with

assistants and suitable apparatus, and a bacteriologist who is familiar with the details of his work as well as a serologist. Without this there is no progress. And the conclusions to be drawn from an incomplete necropsy are almost wholly untrustworthy, and grotesque failures of justice have been recorded from these.

A medical examiner must have training in the examination of scenes, of the body or bodies found there, in the examination of the clothes of the subjects of homicidal assault, in the recognition of the presence or absence of powder grains, and "in bullet wounds he should possess" a working knowledge of firearms and of the distance at which a gun may have been held to inflict a certain type of wound and also whether or not the clothes have more bullet holes than correspond to the number of entrances and exits on the body.

The profession represented by the medical examiner must be authorized to determine the cause of death or any cases under its jurisdiction by necropsy when he deems it necessary. Lawyers and coroners are not qualified to determine this question, as it is a strictly medical one. Fortunately, in New York City we have complete authority and we do not have to ask permission from any one how we should handle any given case. In some states the district attorney is the one to be appealed to for permission. A ridiculous situation since it is a strictly medical problem. Many jurists believe that the cause of death is objective, that an autopsy should cease the instant when the cause of death has been supposedly reached, seeming to hold the view that the cause of death is an object to be removed from the body when seen. There may be more than one possible cause of death which emphasizes the necessity of a complete autopsy.

Truth compels the conclusion that glaring deficiencies exist in the administrations of the coroner's as well as the medical examiner's system. The remedies are known but not easy of application, for the treatment is not entirely in our hands. Experienced pathologists in control with well equipped laboratories and sufficient clerical forces and photographers are indispensable. The public and our legislatures must be educated to the importance of the subject of medicolegal investigation. The value of necropsy must be taught. Unfortunately, the medical profession is somewhat responsible for the antagonistic attitude of the public. The public, to be consistent, should realize that if an autopsy is a desecration, embalming is certainly one.

I am, of course, not opposed to embalming.

What training should coroner's physicians and medical examiners have? A medical degree from an A-1 college. At least two years as an interne in a hospital which gives its internes at least a six months' course of laboratory training in clinical pathology and autopsy work, under a recognized pathologist, at best too short a period of training. All appointees should be civil service, although I admit being in the civil service does not crown him with a halo.

To quote again from Oscar T. Schultz, and I agree with him, it appears extremely doubtful that a comprehensive course in forensic medicine belongs in the regular medical curriculum. The student should have some knowledge of his own legal rights and duties as a physician, and he should have an outline of the relation of his profession to criminology. More detailed and specific training which would fit him for the duties demanded of a coroner or medical examiner should require post-graduate study in an institution organized for such work.

Training for the career as medical examiner, provided the country could be made to realize the importance of this field of work, would demand an amount of time which cannot be fitted into the regular curriculum, and a degree of specialized training which is not the aim of the fourth year medical course.

The situation is similar to that which obtains in public health and sanitation. There must be a demand for properly trained men. There must be opportunities which would make medical graduates wish to elect a career as medical examiner. And there must be facilities for obtaining a thorough training, which would fit him for such a career.

The elective office of coroner, subject to the vagaries of politics, offers no inducements to the physician to enter the field of forensic medicine. The widespread adoption of the medical examiners system with medical examiners selected honestly and retained under civil service regulations would at once open up a new field for which there are not enough qualified persons at the present time.

In conclusion, the opportunity which I hope may be given to intelligent young men in a Department of Forensic Medicine is fascinating and an esprit de corps must be cultivated. This country is fortunate in the institutions which have developed the important phases of scientific progress in medicine.

TUMORS OF THE BREAST, THEIR ORIGIN AND COURSE OF DEVELOPMENT

STEPHEN H. CURTIS, M.D.

Pathologist, Leonard Hospital, Troy, N. Y.

In order to facilitate the presentation of the subject of breast tumors, the author believes it very helpful to first touch upon the normal histology of the breast. The structure of the breast is so much like the sweat gland that it is often spoken of as a modified sweat gland. Derived from the ectoderm, the breast presents at birth little more than a slight eversion of the nipple which elevates it above the skin level. The glands grow equally in both sexes until the age of puberty when those in the male atrophy and only the main duct persists. In the female, the breasts continue to grow and present discoid masses of connective tissue and fat cells with small scattered groups of duct-like tubules.

Pregnancy stimulates the production of the glandular elements. Toward the end of pregnancy each of the branched glands forms a mammary lobe and its alveolo-tubular end pieces are grouped in lobules. The secretory epithelium is a simple cuboidal or flattened layer in which fat accumulates at the seventh or eighth month. It first appears as granules at the basal end of the cell, where it is received in combination from the surrounding tissue. This fat is not produced by the gland cell. The lumen contains leukocytes from the connective tissue which have passed between the epithelial cells. Some of them degenerate; others receive fat from the gland cells, either in combination, or in drops which are devoured by phagocytic action. The fatty leukocytes grow to considerable size and are called colostrum corpuscles. It is from this substance that the colostrum of the newborn and the colostrum of the prepartum period are produced.

Beneath the alveolar epithelium there are basal cells which have been compared with the muscle fibers of the sweat glands. A basement membrane separates them from the connective tissue which contains many lymphocytes and eosinophils. At the termination of pregnancy the gland cells become larger and are filled with stainable secretory granules and fat droplets; the

latter are near the lumen and are often larger than the nucleus. A few days later some of the glands are flat and empty of secretion while others are tall and columnar with a rounded border toward the lumen and occasionally contain more than one nucleus. The fat which is found within the glands is a product of protoplasmic activity and is not due to a secretion or a degeneration.

Transitions between the low empty cells and the columnar forms occur, but mitoses are absent from the lactating gland. Mitotic figures are often seen normally, however, during the pregnant state. When lactation has ended, the connective tissue increases and the leukocytes reappear and form colostrum corpuscles as during pregnancy. The lobules become smaller and the alveoli begin to disappear. In elderly women all the end pieces and lobules have disappeared and only the ducts remain.

The ducts are lined with simple columnar epithelium surrounded by a basement membrane and generally by circular connective tissue bundles. Toward the nipple each duct forms a spindle-shaped dilatation which is called the sinus lactiferus. The outer part of the ducts consists of stratified squamous epithelium. The skin of the nipple and areola at its base contains pigment in the deepest layers of its epidermis. The corium forms tall papillae and contains smooth muscle fibers some of which extend vertically through the nipple, while others are circularly arranged around the ducts. There are tactile corpuscles in the nipple which become rapidly elevated when irritated. This is thought to be due to muscular activity rather than vascular. There are many sweat glands and sebaceous glands in the areola, and occasionally rudimentary hair follicles are found. The areolar glands or glands of Montgomery are branched tubular glands having a lactiferus sinus and otherwise resembling the constituent mammary glands. Their funnel-shaped outlets are surrounded by large sebaceous glands. The areolar glands are regarded

as transitions between sweat glands and mammary glands. Blood vessels enter the mammary glands from several sources and form capillaries around the alveoli. Lymphatic vessels are found in the areola, around the sinuses and in the interlobular tissue. The collecting vessels pass chiefly toward the axilla; a few penetrate the intercostal spaces toward the sternum. The nerves are similar to those of the sweat glands.

With this brief review of the normal histology of the breast in mind, let us turn to the subject of pathology of the breast. The breast may be the seat of origin of inflammatory, benign and malignant tumors. From this angle the breast may be divided into four zones: first, the nipple zone which includes the nipple, the areola, the ducts beneath the nipple and the area of skin immediately surrounding; secondly, the duct zone which includes the epithelial structures between the nipple zone and breast lobules; thirdly, the acinar zone which comprises the acini composing the lobules and the epithelial structures at the termination of the ducts; fourthly, the fibrous zone which includes the intralobular embryonic connective tissue in the immediate vicinity of the acini and the fibrous tissue between the lobules and the fat. Tumors of the breast may be classified as to their origin in one of these divisions.

TUMORS OF THE NIPPLE ZONE

The acutely inflamed swollen nipple of pregnancy, with its reddened fissured appearance, is probably the most common of the nipple effections. The ducts are involved and present the picture of acute inflammation. This process is apt to extend into the duct zone producing acute lactating mastitis, often with abscess formation.

One of the simplest forms of lesion is that involving the external epidermis of the nipple and may be a benign wart or a keratosis. Microscopically they show a hypertrophy of the epidermal layers of the nipple, with much increase in keratin and some small round-cell infiltration. These tumors are due to chronic irritation in which lack of cleanliness plays a large part.

Primary skin eruptions of the eczematoid type may produce an ulceration of the nipple which is characterized by scaling and keratosis. This is usually seen in women over thirty years of age and

may be a forerunner of Paget's disease of the nipple.

Paget's disease is usually secondary to a chronic ulceration of the nipple and is malignant. It begins in the basal cell layers of the skin at the point where these cells have invaginated to form the ducts of the nipple zone. This is a transition point between duct cells and basal cells, and in this transitory phase the malignancy begins. Microscopically, clear, large cuboidal cells without keratin, resembling squamous cell carcinoma are usually seen. This cuboidal cell carcinoma extends on either side of the nipple and involves the neighboring basal cell layers of the skin. It may extend downward into the ducts forming areas of duct carcinoma. The malignancy of Paget's disease is very great and the prognosis is grave. It invades the duct zones of the breast early with relatively early metastasis. In early Paget's

(a) Schematic representations of breast zones
(b) Location of the origin of breast tumors

disease where the tumor is confined to the nipple, radical amputation of the breast may produce a cure.

A pathological dilatation of the ampullae or ducts beneath the nipple may give rise to pain and swelling about the nipple. These ducts may be palpated and feel like nests of worms beneath the nipple. They are found to be filled with mucopurulent material, some of which may discharge from the nipple. Small cystic areas are often found associated with this condition. Infection frequently occurs with pus production. A lymphocytic infiltration occurs in the duct wall. This condition does not ordinarily lead to malignancy. Papillomata growing within the wall of a duct in the nipple zone may give rise to a bloody discharge from the nipple. It is often difficult to palpate these tumors, but they may be easily located by transillumination. The papilloma is found

on section to protrude from the dilated wall of a duct beneath the nipple. It is composed of branches on a stalk from which epithelial duplications are suspended. There is usually an infiltration of leukocytes and fibrous tissue about the dilated cyst wall. The dilatation of the duct may extend deeply into the breast with multiple papillary outgrowths. Some of the cysts may be filled with fresh blood and contain very little of the papillary tissue. A milky discharge from the nipple is indicative of the presence of a galactoceles which may be located deeper in the breast tissue in the duct zone. These cysts may be single but are often multiple. They arise in the proximal portions of dilated ducts but may occur in the ducts just beneath the nipple.

Syphilis and *tuberculosis* of the nipple may occur and present similar pictures pathologically to those infections elsewhere. Some fifteen years ago the author saw a case of a young woman 25 years of age who presented herself for examination because of a small "sore" which had occurred recently on the nipple. It was not painful but did not heal readily. He made a dark-field examination and found the *Spirochaeta pallida* present. The blood Wassermann test was negative. On antileptic treatment, the chancre promptly disappeared. At this point, the patient chose to discontinue treatment. The author did not see her again until the early part of 1933. At forty years of age she has a positive blood and spinal fluid Wassermann with the symptoms of cerebrospinal syphilis.

The question of treatment in these tumors does not ordinarily rest within the duty of the pathologist, but he is often called upon for suggestions. The author will state in a general way his opinion regarding treatment of tumors of the nipple. The warts and keratoses yield very well to soap and water and any measures to promote cleanliness. This also applies to the inflammatory conditions. In those cases in which the results of this method have failed, excision of the nipple is logical. In the ulcerative lesions, early excision of the nipple with a sufficient margin is indicated. The duct cysts should be enucleated as early as possible.

Paget's disease when diagnosed in the early stages before duct involvement may be cured by radical amputation. In the later stages radium and deep x-ray therapy

afford the only means, and this may only be palliative.

The treatment of acute lactating mastitis should be aimed at its prevention. Care of the nipples before the birth of the child in pregnant women to avoid cracking is imperative. In the infected cases the application of ice may abort the abscess, otherwise incision and drainage is indicated.

In chronic lactation mastitis, the pronounced hypertrophy of the acinar tissue has subsided, but the breast remains more or less hard and nodular. These areas present adenomatous tissue surrounded by a small round-cell infiltration. Extirpation of the nodules is indicated for microscopical diagnosis. Mastectomy depends upon this report. Unless malignancy is found, a mutilating operation should not be done.

TUMORS OF THE DUCT ZONE

Dilatation of the ducts may occur at any point along their course. Here the epithelium hypertrophies and becomes piled into a thickness of several layers with a desquamation of the duct cells into the lumen. These duct cells which are thrown into the lumen have a characteristic foamy appearance with a small deeply staining nucleus. Papillary formation may occur giving rise to the so-called introduct papilloma. This condition occurs more frequently, however, in either the nipple or acini zones.

The cysts form from a marked local dilatation of the ducts. The epithelial lining becomes flattened and, in some cases, may atrophy and disappear, thus forming the cyst wall. A marked fibrous tissue proliferation takes place around the wall compressing the surrounding breast tissue. The contents of the cysts vary, and they may be further classified as to their characteristics.

Blue Dome Cyst.—When the cyst wall atrophies and becomes stretched by pressure of its yellowish serous fluid contents, it has a bluish color to its convex surface when first exposed.

Bloody Cysts.—When the cyst is filled with sanguinous material, it is usually significant of a papillary outgrowth of the epithelium. These tumors are usually benign, but occasionally under the microscope the papillary epithelium is found invading the cyst wall and breaking through into the surrounding tissue. These are

called papillary carcinoma or "cancer cysts." Their relation to the benign cyst is somewhat doubtful; some pathologists contend that they do not emanate from a chronic cystic mastitis.

Chronic Cystic Mastitis.—The exact nature of chronic cystic mastitis is difficult to determine. It presents a dilatation of the ducts with cystic formation always accompanied by hypertrophy of the epithelial structures but rarely associated with hyperplasias of the intralobular connective tissue (intracanalicular myxomata). Clinically this condition presents nodules in the breast which are differentiated from malignancy by their multiplicity and variation in size, often assuming considerable size, and then spontaneously disappearing. It is said that two-thirds of all cases of chronic cystic mastitis contain distinct cysts of the breast, usually of the blue dome type and occasionally of the galactocoele.

Galactocoele.—This is a cyst whose contents are of milky character. They are usually found with areas of residual lactating mastitis and are seen in women who have recently borne children. These cysts are often accidentally discovered by the patient. On palpation they are spherical, tense and freely movable and often fluctuation may be elicited. Multiplicity is very common and they may be found in both breasts which is indicative of their benign character. At operation there is often a thin layer of normal breast overlying the lesion which when cut through reveals a bluish color to the cyst, hence the name "blue dome cyst." The contents of the cyst are yellowish, slightly cloudy, and the lining of the wall is distinctly smooth. The surrounding breast tissue may be adenomatous, fibrous, or it may show the presence of dilated ducts. This type of cyst is so characteristic of chronic cystic mastitis that the diagnosis of a benign lesion may be made at operation and an enucleation with a fair margin may be safely done.

Solid Tumor of the Ducts.—Duct adenomata are usually found near the acinar end or nipple end of the duct. They present a proliferation of the epithelial cells filling the lumen and dilating it to varying degrees. This diffuse change of the duct may be "precancerous" in nature. Malignancy associated with this type of tumor is usually of very low grade. Unless the adenomatous cells are found invading

the surrounding tissue, the lesion may be considered benign and another phase of chronic mastitis.

Comedo Cancer.—When malignancy occurs in association with duct adenoma and the cells are of the duct type, it is called duct cancer or comedo cancer because of a resemblance to the common comedons. This tumor does not often metastasize to the lymph nodes, and if a complete operation is performed removing the entire breast and axillary contents, the patient has about an eight to two chance of complete cure.

THE ACINAR ZONE

In this area which represents the alveolar portion of the breast with the branching terminal ends of the ducts, the adenomata are the most common of the tumors occurring here. Nonencapsulated adenoma has little or nothing to distinguish it histologically from the normal breast parenchyma. One of the most definite types of breast adenoma which deserves clinical recognition is the so-called aberrant or axillary breast which is a zone of breast parenchyma forming a swelling in the axillary fold; it may not be noticed by the patient until the hypertrophy of the breast at pregnancy. Multiple indefinite nodules may occur in one or both breasts at the menopause. These are due to isolated islands of breast parenchyma which are more definitely cellular than normal. Microscopically, however, these areas have little to distinguish them from the parenchyma of the normal breast tissue.

Chronic cystic mastitis often involves the terminal portion of the ducts, producing an epithelial overgrowth in the dilated area and resulting in the formation of cysts. These cysts have the characteristic wall with the epithelial lining. At some points, however, there is a reduplication of the epithelium giving rise to the papillary formation. Therefore we may have simple adenoma, adenocystoma, and papillary cystadenoma, according to their histological structures. These conditions usually occur bilaterally and may occur simultaneously. Chronic cystic mastitis with cystadenoma or papillary cystadenoma is called *Schimmelbusch's disease*. This is not ordinarily malignant but in the papillary cystadenoma type, the papillary outgrowths may break through the cyst wall invading the surrounding tissues and taking on the

characteristics of a papillary carcinoma. Ordinarily isolated nodules may be removed, and satisfactory results are to be expected. In diffuse Schimmelbusch disease mastectomy should be performed. The subsequent procedure should depend upon the microscopical findings. As malignancy is not common in these tumors, a cure may be expected.

Medullary and scirrhous carcinoma are the usual types occurring in the acinar zone. They are usually found in the upper and outer quadrants of the breast and therefore are a considerable distance from the nipple. The very cellular growth with a solid proliferation of epithelial cells of the large malignant type are spoken of as the medullary carcinoma. The more common type of cancer in this area is the so-called infiltrating or scirrhous type which is characterized by a marked fibrous tissue proliferation around it with its origin in the terminal acini of the ducts. Microscopically, the cancer cells infiltrate the surrounding lobule and may extend to form islands of tumor separated by the dense fibrous tissue.

The earliest clinical signs of malignancy in a breast tumor of the medullary or scirrhous type is the feeling of a hard nodule some distance from the nipple in the upper or outer quadrant which has caused no pain. In the surrounding structures there is an atrophy of fat with an increase in fibrous tissue which causes dimpling or retraction of the overlying skin with more or less fixation of the tumor. This can often be better demonstrated by requesting the patient to raise the arm above the head. These tumors occur more commonly from middle life onward.

Early mastectomy should be employed if no lymph node involvement is found. When axillary nodes are found with the reddening of the skin about them—the so-called pigskin appearance—the prognosis is hopeless as regards cure. As these tumors are particularly radioresistant, radiation is only palliative. These tumors arising in very late life are less malignant than those arising in the forties and fifties. We have records of 5 cases in which the tumors arose after seventy years of age without metastasis, in which a simple enucleation of the tumor with a wide margin was done, and there has been no recurrence within two years. One of these

patients is alive and without recurrence after five years.

Bloodgood states that "The most competent guide to the experienced surgeon in the diagnosis of early carcinoma is the palpation of a single lump either definite or indefinite which is not accompanied by other lumps of similar character in one or both breasts and which is not associated with the history of disappearance or reappearance. Under such circumstances, the wisest course is to explore and to determine the nature of the tissue of the area by microscopic examination."

THE FIBROUS ZONE

Benign tumors of this region consist of the intracanalicular myxomata and adenofibromata. These tumors arise from the intralobular connective tissue, proliferating within the lobule of the breast tissue and compressing the epithelial structures. They usually finally invaginate themselves into one of the larger ducts. They have a typical myomatous stroma with an early formation of spindle-shaped fibrous tissue cells. Hence the terms myoxoma, myxofibroma, fibroadenoma, etc. Bloodgood refers to a fibroadenoma as a tumor of adenomatous character, definitely encapsulated with a marked proliferation of the interlobular connective tissue. They are definitely circumscribed, hard, with a grayish surface, as distinguished from the pale reddish color of the simple adenoma. They are always benign. The author wishes to distinguish between intracanalicular connective tissue and intercanicular connective tissue. The former is a fine embryonic type of connective tissue found in the immediate vicinity of the acini and terminal ducts. The latter is a more heavy, dense, fibrous tissue surrounding the duct lobules.

Clinically these tumors may be one or several small nodules associated with chronic mastitis. They may also occur singly as an outstanding and prominent tumor of the breast. While usually benign, they may rarely show a change to sarcoma, a point which favors the view that the original pathology is seated in the connective tissue.

Malignant tumors of the fibrous zone consist of colloid cancer and sarcoma. The colloid cancer is a form of breast cancer which grows slowly and is of low-grade malignancy. They are mucoid or gelatinous in character and reach the largest

size of any breast tumor. Microscopically, they show small groups of cancer cells imbedded in a mass of mucoid fibrous tissue. Their exact origin is rather obscure, but some observers have found evidence that suggests a degenerative change in fibroadenoma of long standing. Radical mastectomy is indicated, and the results are quite satisfactory, with many complete cures.

The sarcomata arising from the connective tissue are comparatively rare. Their origin is in the periacinous connective tissue which Virchow compared to the appearance of a cabbage head. Mueller applied to this tumor the term *cystosarcoma proliferum phylloides*. The pericanicular proliferation projects into the dilated ducts and constitutes with the intracanicular excrescences, the proliferating masses. Glandular tissue is sometimes found in the tumor substance which has

grown around it, but is later removed by degeneration and pressure atrophy. These tumors are extremely malignant and metastasis usually occurs. Radiation affords the best method of relief, but the results are only palliative.

In all types of breast tumors the value of biopsy cannot be overestimated. It affords the operator the opportunity of having the report of the pathologist before him at the time and he is in a much better position to determine the logical procedure to follow. Many unnecessary mutilating operations may be avoided in the case of benign tumors which may be doubtful clinically. Likewise, malignancy is determined when present, even though the tumor may be very small, and the patient is afforded the benefit of the proper procedure at an early time. Many cures may be expected at this point when later the condition becomes hopeless.

COURSE IN BACTERIOLOGICAL TECHNIC

Division of Laboratories and Research, New York State Department of Health, Albany

With the development of laboratory science, the need for well-trained technical workers has become increasingly evident. For the past twenty years, the Division of Laboratories and Research has made its resources available to certain grades of students for practical training.

The first regular course offered was given during the World War, in 1918. College graduates with the required background in physics, chemistry, and the biological sciences were accepted for a period of apprentice training combined with reading and study, at the completion of which they were placed in various "war laboratories" throughout the United States. The government found this instruction to be so valuable that, after the Armistice, the Federal Vocational Training Board, the War Department, and other governmental agencies continued to send students to the laboratory.

In 1929, the laboratory was approved by the Secretary of Labor as an institution of learning for immigrant students in accordance with the Immigrant Act of 1924, and hence is authorized to admit foreign students for special training. An applicant may enter the United States for stated periods on a nonquota immigration

visa for study here. The course received further commendation in 1930, when the Committee on Laboratory Service of Governor Roosevelt's State Health Commission reported: "Continuance of the present policy of providing technical training to qualified persons is recommended."

The training offered by the Division of Laboratories and Research is intended to enable properly qualified students to fit themselves for technical positions, especially in public health laboratories; the instruction given does, however, also include many of the methods used in clinical laboratories. The course covers a period of approximately two years. It is given at the central laboratory in Albany, and at the branch laboratory in New York City. There is no charge for tuition but, as students progress, their services are expected to become sufficiently valuable to compensate, to a considerable extent, for the instruction given. Standard methods for all the technical procedures are taught and the practical training is supplemented by reading and study. The museum and the bacterial collection afford opportunities for special study in the pathology of infectious disease. At the semimonthly seminar of the laboratory, the student is brought

in touch with scientific investigations and research work in this laboratory and elsewhere. Students with exceptional training may be permitted to enter the advanced phases of laboratory work and research.

The course begins with instruction for from sixteen to twenty-four weeks, in the preparation and sterilization of glassware and media. This training is fundamental to all work in the laboratory and is an essential part of the training of every bacteriologist. Some students who have not been able to complete the course or who have not been successful in learning the more difficult procedures in the diagnostic laboratories have become, nevertheless, quite proficient in this first step and thus are available for the more subordinate laboratory positions where the routine character of the work admits of the employment of assistants with less knowledge and training.

After completing the training in the preparation of media and glassware, the student devotes from three to six weeks to general bacteriological technic. In the diagnostic laboratories he spends at least forty-two weeks in the study of bacterial diagnosis, clinical pathology, and histological methods, and a minimum of sixteen weeks in the serodiagnosis group, where he is trained in the performance of the complement fixation test for syphilis. The laboratories for sanitary and analytical chemistry provide an eight-weeks' course in the bacteriological examination of water and milk.

By the apprenticeship method, the students gain much practical training as well as a knowledge of the fundamental principles underlying the various procedures performed. A list of students who have satisfactorily completed the course is available at the Division of Laboratories and Research.

TOO VIOLENT TOOTHBRUSHING

That there can be too much of a good thing is shown by the fact that some people brush their teeth so hard that they injure them. Perfectly well-meant advertising has reached a point now where we cannot turn the pages of a magazine, sit in a street car, or pass a billboard, without being urged to brush our teeth. To most people the advice is beneficial, but a certain number of those who read the advertising are enthusiasts, with large, strong hands, who do everything thoroughly and when they go into action with the toothbrush and a large tube of toothpaste, it takes a good tooth to stand up under the attack.

Dr. Isador Hirschfeld, of the Columbia University Dental School, writes of this trouble in *Dental Items of Interest*. These individuals, it seems, go at their teeth with a long, brisk stroke as if they were cleaning the snow off the

sidewalk. They put a pressure on the brush that sometimes breaks the handle, and absent-mindedly do most of the brushing on one spot, denuding the roots of the teeth and forcing the bristles into the crevices. They "lacerate, abrade, or contuse the soft tissue, with resultant cleavage, detachment, or atrophy of the same."

One patient, a muscular young chauffeur, even injured his jaw in his misguided efforts, and a young lady of 30 confessed that she seized the brush in both hands, and used all the pressure at her command. Others selected the largest and hardest brushes obtainable, on the same principle used in buying scrub-brushes or currycombs. As many diseases enter the system because of unhealthy teeth, these habits may profitably engage the attention of the physician as well as the dental surgeon.

FILTHY SCHOOL BOOKS

One unhappy result of reduced expenditures for educational purposes, remarks the *School Physicians' Bulletin*, is that thousands of children are using textbooks which have become not only unsightly but also unsanitary.

This was reported at a conference on better hygiene in handling books used in common in schools, held at the call of United States Commissioner of Education George F. Zook. Need of immediate attention to this problem was suggested to Commissioner Zook by prominent club women.

The useful life of an elementary school textbook, it was pointed out, is approximately three years.

The conference urged that the relatively small

outlay for textbooks and other material handled by children should not be reduced and that facilities for cleanliness of school children should be made ample.

While it was reported that studies undertaken to date fail to furnish positive proof of transmission of disease through common use of textbooks, the conference asked that school administrators put forth more efforts to prevent children with infectious diseases from being in school and to insure safer handling of books by children.

The Federal Office of Education was requested to prepare a circular on the supply and handling of textbooks for the information and guidance of school administrators and civic groups interested in the schools.

NONOPERATIVE PHYSICAL MEASURES IN GYNECOLOGY

MADGE C L MCGUINNESS M D

New York City

Correct diagnosis and a knowledge of the underlying pathology are absolutely essential to a proper application of physical measures

The constitutional inferior will react entirely differently to these measures in comparison with the normal woman. It is therefore necessary to consider the patient as a whole, the type of constitution and the extent of insult to the central and vegetative nervous systems as well as the endocrine and circulatory balance.

The inferior constitution manifests itself in maldevelopment, asthenia, and endocrine imbalance. Malnutrition, infectious diseases, child labor, and overstudy likewise prevent normal development. We have then the infantile uterus with amenorrhea, oligomenorrhea, sterility, habitual abortion, and early menopause.

The asthenic constitution, especially if the nervous systems be at fault, makes for lowered resistance. The poor posture, poor musculature, visceroptosis, and profound weakness with their train of ills as dyspepsia, constipation, colitis, dysmenorrhea, backache, and headache are all heightened by the asthenic nervous systems.

Endocrine imbalance is a common cause of ill health in women. In the last analysis, it is the ovary that makes for health or lack of it. Hyperfunction causes hemorrhages whatever the local cause. Dysfunction causes dysmenorrhea. Hypofunction makes for disturbances of menstruation and sterility.

AMENORRHEA AND OLIGOMENORRHEA—These conditions are amenable to physical therapy when due to anemia, endocrine imbalance, underdevelopment, and psychic disturbance as fear, worry, grief and fright and the arthritis of puberty and the menopause. A primary amenorrhea not corrected by the age of 25 is usually difficult to overcome.

In addition to the accepted dietary and medical measures and physical therapy in the form of rest, heliotherapy, phototherapy, hydrotherapy, exercise, and general body building, electrotherapy is indicated.

Locally, intrapelvic diathermy is used to cause hyperemia. A belt electrode encircles

the hips and a special electrode is placed in the vagina or rectum. Treatment is given twice or thrice weekly for two weeks before the expected period for about 35 to 45 minutes.

The treatment of choice is the stimulating static wave given from the negative pole for 15 minutes, abdominally, vaginally, or rectally.

When the static is not available, use the direct current with the negative pole in the vagina, cervix or rectum for 15 minutes with 20 ma of current for 9 to 12 treatments. Either the sinusoidal or Morse wave giving forty to fifty interruptions per minute is employed for ten minutes to improve muscular tone.

Phototherapy—Infra red to the abdomen, 30 to 45 minutes, thrice weekly, in place of diathermy or on alternate days has been employed with benefit.

Hydrotherapy—In the form of sitz-baths, 60 to 70° F for two to four minutes with friction to the abdomen or the warm sitz 98 to 104° F for 15 to 30 minutes, depending on the case. Cold compresses of about 60° F left on all night followed by a cold ablution in the morning are often of service.

Exercises—Exercises for general and local effect must be carefully prescribed and graded. They should begin with the simplest forms to help circulation and muscular tone. Nothing strenuous nor fatiguing. Frequent rests and relaxation are necessary.

Massage—General and local will be of great service, especially in the asthenic patient. Gentle stroking is best.

LEUKORRHEA—This is but a symptom of many conditions and can be treated properly only if the cause be found. It may be evidence of impaired local tone, due to circulatory disturbance and requires local treatment as well as attention to the cause.

Discharge arises chiefly from cervical infection, less often from the fundus, vulva, or anus, but rarely from the vagina. The vaginal discharge proper is thin, foamy, and yellow in color. When otherwise, infection has taken place from pes

saries or other foreign bodies, or other contamination. Cervical discharge is always thick, the uterine thin. A vaginal discharge may occasionally require a douche, but the other conditions are not effected by douching at all. In obstinate cervical discharge copper or zinc ionization is indicated as elsewhere described.

VAGINISMUS.—Although this is largely psychic, it can be very effectively helped with the static wave current. The technic of this treatment is especially important. No ground is used and a glass vacuum electrode is connected with the negative pole. At first a small rectal electrode is used and later graduated vaginal electrodes can be introduced. It has been found advantageous to have the patient insert the electrode herself and at each seance a larger one is given her. Manual examination should be avoided until the last visit. This final examination tends to convince the patient that the irritability is then under mental control. The rectal electrode used at first is cone-shaped at the end, widening out to $\frac{1}{2}$ inch in diameter. Although not a gynecological condition, it is worth drawing attention to the original use of this electrode with the same technic in dilating the anus for the re-insertion of painful protruding hemorrhoids. Dr. Norman Titus originated this technic.

HEMORRHAGES.—In adolescence, general body building will usually remove the cause. In the menopause, having ruled out growths, attention to hygiene, general, mental, and physical is required. Physical therapy is of service in menorrhagia and metrorrhagia due to uterine and adnexal inflammation, subinvolution, or any condition giving rise to relaxed and patulous blood vessels of the pelvic viscera.

Intrapelvic diathermy for 35 to 45 minutes followed by the direct current with the positive pole in Douglas's cul-de-sac, the negative electrode on the abdomen, is employed for 10 to 15 minutes, 20 ma. thrice weekly. The positive pole will also exert a favorable influence on inflammation checking its further formation. The sinusoidal may follow the direct current for its toning effect but it is preferable if it can be combined with the diathermy. Heat therapy between periods may be employed to reduce any inflammation due to infection in the subacute and chronic forms. It may take the form of diathermy, Elliott's treatment, phototherapy, radiotherapy, etc.

STERILITY.—*Male sterility* is responsible for from 27 to 50 per cent of sterile marriages. Therefore, it is essential to rule out this condition before treatment of the wife alone is instituted. While gonorrhea is probably the most common cause, many others may be operative: parotitis and the chronic debilitating diseases such as nephritis, diabetes, tabes, alcoholism, and drug addictions are frequent. Neurasthenia, profound fatigue, worry, anxiety, and overwork are factors likewise found. These latter are amenable to tonic baths as a cabinet, Scotch douche, spray and shower, stimulating and sedative baths when indicated, general daily exercises, heliotherapy, aerotherapy, and the other upbuilding measures. Rest and relaxation are of prime importance. Diathermy and radiotherapy are also of service.

Female Sterility.—Blocked tubes, chronic cervicitis, pelvic inflammation, underdevelopment, etc., are among the chief causes of sterility.

Prolonged work, worry, shock, confinement indoors and lack of rest reduce the general metabolic activity causing profound fatigue. Decreased nutrition, obesity, any intoxication, malnutrition, and laziness are outstanding factors.

Pelvic inflammation of whatever nature must be corrected before testing for tubal patency. Radiotherapy, pelvic diathermy, prolonged douching, phototherapy, the hot sitz bath will be of service in all inflammatory conditions. Nongonococcal cervicitis may require ionization to clear up the discharge. In underdevelopment, general measures for building up must be instituted and, locally, pelvic diathermy 40 to 50 minutes for the tonic effect on the ovary and uterus, followed by the direct current with the negative pole in the cervix. When followed by the sinusoidal current for 10 to 15 minutes, muscular debility, circulatory and lymphatic stasis are favorably influenced.

ANOMALIES OF UTERINE POSITION

Marked *anteversion* is due to subinvolution and adhesions and causes frequent micturition and bearing-down pains. Relief is obtained by reducing the size of the organ and relieving tension due to adhesions.

Pelvic diathermy is followed by the static wave given rectally. The positive pole is connected to the patient, the spark gap begins at one inch and is gradually widened to tolerance. Never cause pain.

it is the rhythmic contractions that make for pelvic and systemic adjustment.

Marked *anteflexion* is congenital as is shown in the underdeveloped uterus which causes severe dysmenorrhea, backache, and abdominal colic. Oligomenorrhea with clotting is frequent.

General treatment is needed in this condition. Surgical curettage affords relief for varying periods. If the building-up process fails to relieve, dilatation and stimulation of the underdeveloped uterus by the negative pole of the direct current may be done preceded by pelvic diathermy for the effect on the ovary.

Acquired anteflexion requires treatment of the underlying parametritis. Here pelvic diathermy is the treatment of choice.

Retroflexion and *retroversion* with or without fixation of the uterus may be due to infection, subinvolution or an atonic condition of the pelvic muscles and ligaments. Resting upon the rectum it may be irritated by the feces and likewise cause constipation and hemorrhoids.

Intrapelvic diathermy is indicated followed by the static wave.

Exercises.—The knee chest position with its variations is most helpful in these conditions.

DYSMENORRHEA.—Painful menstruation may be primary with no demonstrable pelvic lesion or secondary due to any pelvic disturbance as malposition, tumors, or inflammation. Clinically we have endocrine, spasmodic, and congestive dysmenorrhea. The endocrine shows itself in a multiplicity of symptoms due to glandular dysfunction and the accompanying nervous irritability.

Spasmodic dysmenorrhea is that present in young girls and childless women with marked anteflexion and retroflexion. These may also show underdevelopment or neurasthenia.

The congestive type while present in pelvic inflammation, is especially common in those leading a sedentary life with its attendant constipation and those in whom sexual or marital disturbances make for instability.

Many cases of dysmenorrhea complain of nasal disturbance and when this is treated, dysmenorrhea is relieved. Cauterizing the "genital spots" of Fliess which are on the anterior portion of the inferior turbinate and the tuberculum nasi frequently clears up the cramps and severe pain. Test out with two drops of 10 per cent cocaine solution and one drop of

1:1000 adrenalin solution sprayed into the nose. After 10 minutes the turgid membrane shrinks and the pain is relieved sometimes 8 to 10 hours; sometimes for the entire period, sometimes completely. Repeated tests showing the same result call for cauterization or electrolysis. The most suitable cases are those with marked vasomotor and nervous disturbances who complain, after the period starts, of severe cramps, nausea, vomiting, abdominal discomfort, dizziness, and headache or migraine. This has been called "nasal dysmenorrhea" by Novak*.

General Treatment.—In all cases of dysmenorrhea, measures for building up the patients' general condition play an important part. In addition to appropriate medication, this is best done by rest, dietary measures, sports and outdoor living, graded exercise, general hydrotherapy measures, phototherapy, etc.

Preventive medicine has a large place in the treatment of dysmenorrhea. When girls are brought up to realize that menstruation is a physiologic and not a pathologic process and that normal pursuits, exercise, and bathing are permissible at that time, we will have less need to resort to curative measures. Girls who have learned that it is not the sporting thing to be ill have gone a long way toward solving their problem and preventing "nerves."

To prevent dysmenorrhea as well as all other feminine ills, strictest attention should be paid in the formative years from 12 to 20 to the girl's mode of life. A correct posture must be insisted upon at all times. Healthful outdoor games for *sport*, not for *records*, graded exercises and proper rest and relaxation, thus assuring proper development and team work for the mental stimulation will help greatly. Not too strenuous nor heavy work should be undertaken at the period but ordinary pursuits and the usual gymnastic work may be continued.

Bathing is not only permissible but necessary. Sponges and showers certainly at first, though a bath pleasantly warm should be the rule rather than the exception from the second day on.

I know of no greater mistake than to permit girls to be excused from physical exercises at school or college "because these are just a waste of time." The girl suffers from this all her life, she loses the discipline of muscle and mind that should

* Novak "Menstruation and Its Disorders," D. Appleton Co., 1922.

be the major part of her education and, if excused because of menstruation, a physiological process is thrust forcibly into the foreground of consciousness.

Acceptance of health, life and its processes with less discussion of its functions and then only with the medical adviser, will make for healthier and happier women.

Girls of an asthenic constitution will need much rest to regain lost tone, massage, carefully graded exercises instead of strenuous sports, much sleep, careful feeding, freedom from worry over work not well done and, above all things a cheerful disposition instead of the whining one so prevalent. Health may be achieved with care and patience.

Local Treatment.—Inflammatory disease of whatever origin will be found most amenable to local physical measures as will, also, congestion, stenosis, malpositions and ovarian dysfunction. Locally, at the onset of pain, hot compresses to the abdomen, warm douche, 110° F., or warm enema or a hot sitz bath, 105 to 110° F., or infra-red radiation from 30 to 60 minutes, may be of service.

In anticipation of the condition, however, electrotherapy may be instituted to correct the flexion and stenosis. Pelvic diathermy followed by the static wave will afford much relief. Use the direct current if the static is not available.

INFECTION.—The streptococcus, gonococcus, *coli communis* and diphtheroid bacillus are most often found. The neisserian is the most important as it is the commonest and most disabling of the infections. Dry heat in the form of radiotherapy, diathermy, Elliott's treatment and radiant and infra-red rays, continuous douches, sitz baths, etc., have been employed. Radiotherapy has been used locally in but a few cases in which there has been time to study it—the procedure is still in its infancy in this field—but so well have these reacted that it may well become the method of choice for those who can afford hospitalization and who are good risks.

PELVIC INFLAMMATION is usually due to infection which may manifest itself in exudate, adhesions or in displacement of the pelvic organs including intestines and omentum.

CERVICITIS.—Copper or zinc ionization is indicated depending upon the amount of

discharge and bleeding. For bleeding, use a copper sound as a positive pole, the large negative electrode to the abdomen. If the discharge be profuse and septic, use the zinc as the positive pole. The current is turned on very slowly, begin with 5, work up to 20 ma. for 15 minutes. In case of pain, reduce the current at once. Persistent pain means there is involvement of the ovaries or tubes requiring further examination to rule out surgical conditions.

CERVICAL EROSIONS may be treated at the same sitting with the zinc electrode, or the water cooled ultra-violet applicator applied directly to the cervix will induce healing. Several treatments clear up the discharge and all signs of the vulvovaginitis disappear as well.

After ionization one should wait two to three days to be sure any reaction has subsided. Repeat if needed. Rest in bed for the day of the treatment is desirable. Difficulty may be experienced in withdrawing the positive electrode from the cervix at first. Wait a few moments. If still adherent, turn off the current. Reverse the polarity. Turn on the current for two to three minutes up to 5 ma. The electrode can then be withdrawn easily. Should we wish to denude the cervix for any reason, the positive electrode may be withdrawn with slight force by turning off the current and waiting for a few minutes then turning the electrode gently to and fro to release. The bleeding is usually negligible, but in case of too much bleeding, a light packing of iodoform gauze may be inserted into the cervix with the usual aseptic precautions.

TECHNIC

Physical measures are used principally to relieve vascular and muscular spasm, to remove obstruction and promote drainage. To this end, the usual procedure is to first induce hyperemia thus causing a cellular response that manifests itself in chemical activity, change in secretion, and increased resistance.

In most of our cases the patients are in subnormal condition so that for the systemic effect we find it of advantage to give a general treatment by autocondensation, 300 to 600 ma. for 10-12 minutes, or general radiation with infra-red or radiant light before instituting other measures.

General ultra-violet radiation is of great value in all these cases, as is also the static. Hydrotherapy, massage, and exercise must

be carefully prescribed. Exercises of the simplest character, a few at a time, carefully rehearsed and graded will do much for upbuilding.

Pelvic Diathermy—In applying diathermy for pelvic inflammation the method of choice is the 3 inch belt around the hips as the directing electrode with the active electrode in the urethra, cervix, vagina, or rectum. Connected plates over the pelvis and the sacrum are used by many physical therapists instead of the belt. Diathermy is most effective if it is given in gradually augmented dosage increasing at 2 or 3-minute intervals until the required milli-ampere is reached. The reason for this is as follows: there is a gradual rise in temperature from the time the current is turned on until a certain height is reached, there is then a proportional drop to a probable optimum which is maintained for as long as the current is applied unless the patient grows restless when it rises slightly again.

It may take 4 to 6 minutes to reach the peak with a corresponding time to drop, so that unless a long treatment be given, the patient is not receiving the length of time specified nor the amount of current ordered. A long slowly arrived at maximum is best. When the current is turned on quickly and the peak reached quickly, the drop is proportionately rapid and much lower and the current slowly rises again. There is not the steady, sustained flow that seems most effective, and the patient does not bear high amperage so well (see experiments of Dr Derow).

The vaginal electrodes are of several types, the Chapin, Cherry, Cumberbatch, Corbus and O'Connor, Derow, etc. Derow has modified the usual aluminum electrode so that it is serviceable in several ways. It is in two sizes, for the nullipara and multipara. It has been broadened out with a shallow curve that insures dispersion of the necessary heat through the cervix, uterus, and adnexa. It has been hollowed out for two thermometers one for a direct reading from the central axis and a side opening for the indirect. Most important is that it may be used interchangeably and even simultaneously for diathermy and the direct current or sinusoidal.

The aluminum may be copper-plated and this may be amalgamated with mercury as follows: make up a solution of nitric acid $\frac{1}{4}$, water $\frac{3}{4}$, and a few drops of metallic

mercury. Dip the electrode in this and it will have a coating that is antiseptic, less astringent than copper or aluminum, and that does not stick. Sterilization is unnecessary as a new plating is applied before each treatment and no lubricant is required.

Technic of Dr. Heinrich Wolf—By this method the patient sits on a chair, the perineum resting on a saline soaked towel which is placed on a sheet of block tin accurately molded to fit the part. The directing electrode is a belt around the waist. The patient controls the current which is gradually increased to tolerance and then maintained for thirty minutes.

DIATHERMY IN GONOCOCCAL URETHRITIS AND CERVICITIS *The Cumberbatch Method*—The belt electrode is of block tin 3 inches wide to be placed around the hips. The urethral electrode consists of a rod 6 inches long, $\frac{3}{16}$ inch in diameter. The end for urethral insertion is $1\frac{1}{2}$ inches long, an ebonite disk 1 inch in diameter, marking the length to prevent entrance into the bladder. The outer end of the urethral electrode is attached to a stand placed between the thighs and connected to the diathermy machine. The stand prevents strain or pressure on the urethra which is most important. A thermometer may be inserted in the electrode to record the temperature.

The cervical electrode is made of tin to permit easy insertion at any degree of flexion or version required. It is covered almost its entire length of 12 inches by rubber tubing except the $\frac{3}{4}$ of an inch of the cervical end.

The urethral electrode is inserted into the urethra up to the disk and supported by the stand. The belt electrode of block tin 3 inches wide is placed around the hips on a level with the urethra. The current is gently turned on and gradually increased until the patient can just bear no more—the heat is being replaced by pain. The current is slowly reduced until only the heat is sensed. This is maintained for 10 minutes. *Note the amount of current.* Pain is felt usually between 114° and 115° F. In many patients it is complained of before this figure is reached, to tolerance only is the rule, whatever the temperature.

The cervical electrode is inserted into the cervix for $\frac{3}{4}$ inch and attached to the stand, care being taken to cause as little pain as possible. The current is slowly turned on until one half the amount used

in the urethra registers. The cervix is insensitive to heat, and only the same intensity of current is used as in the urethra, the cervix being one-half the length of the latter. The current flows for 10 minutes.

In case of pain in the tubes or ovaries, diathermy with the intravaginal electrode precedes this treatment for 30 minutes. Usually 6 to 10 treatments are required depending upon the regularity of the patient's visits and her care at home.

Frequent examinations one or two days after menstruation for 3 to 5 periods are necessary after the completion of the treatment which is usually given twice or thrice weekly until 6 to 9 are given. Examination should include the ducts of Skene as well as the urethra and the glands of Bartholin as well as the cervix and vagina. A course may have to be repeated, most certainly if reinfection has taken place. If Skene's ducts and the Bartholin glands are harboring a nidus they may be cauterized to shorten procedures.

The Corbus and O'Connor Method.—A cervical temperature of 116° to 117° F. is operative for 30 to 40 minutes in these cases for a complete eradication of the gonococcus. Five negative smears following a course of treatments must be made. Treatments are given about once in 7 to 10 days and vary from 1 to 14—four to seven being the average. This method is especially applicable in cases of cervicitis.

Arthritis that does not yield to ordinary treatment of the joints frequently is relieved by treating the original site of infection as the urethra or cervix first. If then the urethral and cervical condition is cleared up, the joints may be treated, if needed, later. Some cases of sciatica and neuritis have likewise cleared up under the Cumberbatch treatment.

Experience at the Vanderbilt Clinic has shown that diathermy by the Cumberbatch method is superior to other forms of treatment in acute and chronic neisserian infection and its sequelae.

HYDROTHERAPY IN GYNECOLOGY.—Hydrotherapeutic measures have always enjoyed a large measure of popularity in gynecology in the form of vaginal douches, enemata, sitz baths, compresses, packs, and the usual general baths and their modifications.

It is surprising how little is really comprehended when the order for these measures is given. Douches in the upright

position have been taken for years by patients who announce very firmly they have not been otherwise instructed. Hot baths are taken indiscriminately where tepid or cold are indicated. Water in any form has been taboo in menstruation and this may be the rock on which treatment will split if a determined mother, grandmother, friend, or neighbor has a more persuasive personality than the physician however well armed with science and common sense.

A prescription written out and explained in the minutest detail is absolutely essential and a check up of procedure more so. It may be necessary to direct or give personally the treatment at first.

Do not take for granted the knowledge of the attendant unless cognizant of her training and character. Failure is the rule rather than the exception with the woman patient who is too ill or nervous or bothered or lazy "to submit to all that nuisance that everybody knows and does." The usual complaint is "I've done all that and it never helped."

When it is considered that excessive hot douching frequently causes or increases leukorrhea, the point in this regard may be well taken. Hence the need for direction as to *why* and *how* and particularly *when* and *how often* a douche should be taken. Repetition depends here as in general upon the effect of the initial procedure.

The Vaginal Douche.—This is the commonest of hydrotherapy measures, the most abused and least understood. Its indiscriminate and too frequent use is to be condemned. It must always be taken lying down and never unless this position can be maintained for at least 20 to 30 or more minutes. It is useless to run in quickly several quarts of water or to force them in while in the sitting position. A long, warm douche, slowly flowing from a height not greater than 12 to 15 inches above the patient's pelvis will help materially to increase her comfort and allay her inflammation and pain. The temperature may be raised from 98° to 110° to 115° F. depending on the pathology and may be given in amounts varying from 3 quarts to 5 gallons, daily or twice or thrice weekly as indicated. Protect the vulva and perineum with vaselin and thick towels or use a special speculum.

The douche is preferably taken at bedtime or when complete rest for the quite relaxed organs may be assured. If a

strained position is assumed either on the douche pan or in the tub, little good will be done and much complaint of the fatigue, backache, and general discomfort. A pile of newspapers or a firm pillow covered with rubber or oil cloth, a pillow at the back and the feet supported will obviate this. The bathroom should be quite warm and a covering should be arranged over the tub—a heavy quilt generally—to prevent taking cold.

The continuous douche is used for inflammation, especially chronic, pain, and hemorrhage. If medication is added it is usually an antiseptic as chlorazene, lysol, tincture of green soap, lactic and boracic acid, etc. Soda bicarbonate is frequently used, especially to dissolve mucus and allay pruritus. No strong medicaments, such as bichloride of mercury or carbolic, should be allowed for obvious reasons.

A soda bicarbonate douche is frequently used to temporarily neutralize vaginal acidity in sterility. Astringents, such as zinc or copper sulphate, 2 drams to one quart, tannic acid, $\frac{1}{2}$ dram to one quart, or liquor aluminii acetici, $\frac{1}{2}$ dram to one quart, have a wide vogue.

Proper cleansing of the douche apparatus must be impressed upon the patient. The nozzle, preferably of glass, should be boiled before and after using. The metal irrigating can is superior to the rubber bag. Boiling in a bag is safest, the whole being allowed to dry and kept ready for use to prevent contamination.

Baths.—These have a decided place in the general upbuilding of the nervous, neurasthenic, anemic, asthenic patient. Girls and women must be taught the use of the warm, hot, cool, and cold bath, wet packs, sponges, and showers.

The warm bath about 98° to 100° F. is especially indicated in the asthenic and neurasthenic patient at night for its sedative and soporific effect. The hot bath with the temperature increased from 98° to 104° F. for 5 minutes followed by the warm pack until free perspiration is induced is excellent for the anemic patient. The salt glow as practiced at Battle Creek is particularly stimulating.

Cool and cold baths, sponges, showers, and packs are best given in the morning. The neurasthenic, anemic patient responds well to these if they be given tactfully and properly, no matter what the initial objection may be. Begin first with the cool sponge, then the dry pack until warm, with

friction preferably, then rest. Cold baths with friction are excellent for obese patients who are spurred to renewed exertion and in those at the menopause especial benefit is claimed.

Rest and relaxation should give a good reaction after these measures, and they may then be continued.

The Sitz Bath.—The warm sitz bath is given at a temperature of 98° to 104° F. usually for 10 to 30 minutes. It is excellent as a sedative, to relieve spasm and cramp, to allay inflammation, to favor absorption of exudates, to increase blood supply, relieve congestion. It is therefore indicated in amenorrhea, oligomenorrhea, dysmenorrhea, backache, leukorrhea, pelvic inflammations, etc. The hot sitz, temperature 104° to 110° F. is for more decided action. The temperature must be raised gradually and care must be taken to prevent chilling.

Cold Compresses.—These are excellent in all acute inflammation especially where pain is complained of, hemorrhage and infections are especial indications, 40° to 50° to 60° F. may be used, depending upon the tolerance of the patient. Warm and hot compresses may be used for dysmenorrhea, amenorrhea, exudation, etc., where the sitz bath cannot be taken; 98° to 104° to 110° F. is the temperature, depending on the severity of the lesion. These compresses may be kept on for hours at a time.

CONCLUSIONS

1. Be sure of the diagnosis.
2. Treat the patient, not the condition alone.
3. Give the treatment long enough to do some good.
4. Give explicit directions for home treatment, exercises, hydrotherapy, etc., and see they are carried out.
5. Diathermy is not a cure-all, but is of particular value in gynecology. It is the method of choice in acute and chronic neisserian infection and its sequelae for clinic and office practice.
6. When muscular stimulation is wanted, the static wave current is the method of choice. The slow sinusoidal current can be expected to bring about somewhat comparable effects. However, the latter does not have the accompanying decongestive action which is essential.
7. Galvanism has its greatest field of usefulness in gynecology.

HOUSE OF DELEGATES

MINUTES OF THE ANNUAL MEETING

May 14 and 15, 1934

The 128th Annual Meeting of the House of Delegates of the Medical Society of the State of New York was held at the Hotel Utica, Utica, New York, on Monday, May 14, 1934 at 10 A. M.

Dr. Samuel J. Kopetzky, Speaker; Dr. Daniel S. Dougherty, Secretary.

THE SPEAKER: The House of Delegates will please come to order.

1. COMMITTEE ON CREDENTIALS

THE SPEAKER: The first order of business is the report of the Committee on Credentials.

THE SECRETARY: The Committee on Credentials finds no disputed delegations, and all those whose names are on our roll are entitled to vote.

THE SPEAKER: The next order of business is calling the roll.

THE SECRETARY called the roll by counties.

THE SPEAKER: A quorum being present, we will proceed with the business of the House.

2. APPROVAL OF THE MINUTES

THE SPEAKER: The first order of business is the reading of the minutes of the previous meeting.

THE SECRETARY: As these minutes have been published, I move that the reading be dispensed with and that they be adopted as published in the May 1st, 1933 issue of the NEW YORK STATE JOURNAL OF MEDICINE, page 581.

Motion seconded and carried.

3. REFERENCE COMMITTEES

THE SPEAKER: The Secretary will now announce the Reference Committees.

The secretary read the following Reference Committees:

REFERENCE COMMITTEE ON REPORT OF THE
PRESIDENT

John J. Buettner, *Chairman*, Onondaga
Albert A. Gartner, Erie
Samuel M. Kaufman, New York
Edgar A. Vander Veer, Albany
Warren Wooden, Monroe

REFERENCE COMMITTEE ON REPORT OF SECRETARY,
COUNCIL AND COUNCILLORS

William A. Krieger, *Chairman*, Dutchess-Putnam
Louis F. Garben, Suffolk
H. P. Mencken, Queens
John T. Donovan, Erie
John E. Jennings, Kings

REFERENCE COMMITTEE ON REPORT OF TREASURER
AND TRUSTEES

Walter T. Dannreuther, *Chairman*, New York
J. Lewis Amster, Bronx
James H. Donnelly, Erie
Murray B. Gordon, Kings
Edward T. Wentworth, Monroe

REFERENCE COMMITTEE ON REPORT OF LEGAL
COUNSEL

George A. Leitner, *Chairman*, Rockland

William A. MacVay, Monroe
Augustus J. Hambrook, Rensselaer
George S. Towne, Saratoga
Wilbur G. Fish, Tompkins

REFERENCE COMMITTEE ON REPORT OF COMMITTEE
ON PUBLIC RELATIONS

Denver W. Vickers, *Chairman*, Washington
William J. Doerfler, Westchester
Luther C. Payne, Sullivan
Louis A. Friedman, Bronx
Alfred E. Shipley, Kings

REFERENCE COMMITTEE ON REPORT OF COMMITTEE
ON PUBLIC HEALTH AND MEDICAL EDUCATION

George R. Critchlow, *Chairman*, Erie
Walter D. Ludlum, Kings
Franklin Walker, New York
George M. Fisher, Oneida
W. Grant Cooper, St. Lawrence

REFERENCE COMMITTEE ON REPORT OF COMMITTEE
ON LEGISLATION

John J. Masterson, *Chairman*, Kings
Frederic W. Holcomb, Ulster
Edward R. Cuniffe, Bronx
Robert E. DeCeU, Erie
Terry M. Townsend, New York

REFERENCE COMMITTEE ON REPORT OF COMMITTEE
ON SCIENTIFIC WORK AND ARRANGEMENTS

Arthur F. Heyl, *Chairman*, Westchester
Nathan Ratnof, New York
Harold J. Harris, Essex
Clarence V. Costello, Monroe
David W. Beard, Schoharie

REFERENCE COMMITTEE ON REPORT OF COMMITTEE
ON ECONOMICS

James F. Rooney, *Chairman*, Albany
Charles C. Trembley, Franklin
Robert B. Hammond, Westchester
Howard W. Davis, Broome
David J. Kaliski, New York

REFERENCE COMMITTEE ON NEW BUSINESS A

Edward C. Podvin, *Chairman*, Bronx
Carl Boettiger, Queens
C. Knight Deyo, Dutchess-Putnam
Leo F. Schiff, Clinton
James W. Sweet, New York

REFERENCE COMMITTEE ON NEW BUSINESS B

Luther F. Warren, *Chairman*, Kings
Reeve B. Howland, Chemung
DeForest W. Buckmaster, Chautauqua
Adolph G. DeSanctis, New York
Romeo Roberts, Westchester

REFERENCE COMMITTEE ON NEW BUSINESS C

B. Wallace Hamilton, *Chairman*, New York
Edward A. Sharp, Erie
William Howard, Albany
George C. Vogt, Broome
James W. Bulmer, Nassau

CREDENTIALS

Daniel S. Dougherty, *Chairman*, New York
Peter Irving, New York.

THE SECRETARY I move that the reports of the officers and committees be sent to the Reference Committees as printed, without reading

Motion seconded and carried

THE SPEAKER If any of the officers or committee chairmen have supplementary reports to present I take pleasure in extending them the privilege of the floor

4 SUPPLEMENTARY REPORT OF THE TREASURER

Section 38

DR SONDERN *Gentlemen of the House* As customary, your Treasurer has made the usual report to the Board of Trustees and it has been published in approved form I ask for the privilege of a few words concerning it Additional details will be furnished to your Reference Committee so that they may be conversant with any complete portion of it that they wish I would like to say a few words to you at this time relative to your war chest

Through the wisdom of your past action you have been fortunate in accumulating a sizable war chest It has been well conserved by your Trustees, but I would like to urge on you the necessity to increase this fund We are in troublesome times For example, you may be called upon at any time to oppose legally, such a thing as the corporate practice of medicine and if so, it will necessitate the expenditure of a considerable amount of money

You may wish to make studies similar to those recently made in Michigan that cost \$15,000 or \$20,000, more than the entire dues of the Society for the year Therefore, I would like to urge upon you again to maintain, and, if possible, increase this fund

Through the wisdom of this House you have accomplished a considerable economy, which is not apparent in the 1933 Treasurer's Report You will recall that for 1933 the total cost of the STATE JOURNAL was \$18,915 or approximately \$19,000 That was made up by the allocation of one dollar per member per year and a deficit of \$6,218

With the changes that you have made that account this year will read about as follows

Allocation for cost of producing the JOURNAL, fifty cents per member amounting on the basis of last year's membership to \$6,348

On a four and one half months' experience we find that the expenses of your Journal Management Committee can probably be covered by an additional twenty five cents per member, amounting to \$3,174 or making a total cost for the JOURNAL of \$9,522 and a saving over last year of approximately \$10,000

I have no doubt but that a careful consideration of the entire matter of expenditures will lead to additional savings, but let your retiring Treasurer impress this on you, keep your war chest in order for safety and protection

THE SPEAKER We are now ready to hear the address of the President

DR. FLAHERTY *Mr Chairman and members of the House of Delegates* The address of the President will be read tomorrow evening but I am glad to meet you this morning and receive your hearty welcome I feel I hardly deserve it However, I am delighted to see such a large group of men present It is a forecast of a good meeting

THE SPEAKER Gentlemen, I now take pleasure in presenting the President elect

5 ADDRESS OF PRESIDENT ELLIS

Section 56

DR BEDALL *Mr Speaker and members of the House of Delegates* It is with a deep sense of gratitude and appreciation that I address you this morning

Your expression of faith by electing me your President I take as an indication of your willingness to cooperate, and for this I am indeed thankful When I consider the contending forces which are at work to weaken or destroy the practice of medicine, I am conscious of my responsibility

I pledge my allegiance to the constitution of the Medical Society of the State of New York and especially, to extend medical knowledge and advance medical science, to elevate the standard of medical education, to secure the enactment and enforcement of just medical and public health laws, to promote friendly intercourse among physicians, to guard and foster the material interest of its members, and to protect them against imposition, and to enlighten and direct public opinion in regard to the problems of medicine and public health

The height to which the lofty aims of our Society may rise depends upon the efforts of every member We are in the midst of clashing factions There are some who gaze into the distance and see visions of few obligations, little work and much pay They, I fear, are deluded by fantastic dreams

The sessions of the House of Delegates will give all an opportunity to express themselves and in the end I trust that the majority will rule against further experimentation in the practice of medicine There is no question in my mind but that the socialization of medicine eventually means the death of the patient

There are no reasons why the profession of medicine should change its established order because of a temporary depression from which we will emerge if only given a chance The basic underlying economic unit of our State is the home The relations of this group have not changed, nor have the essential elements of religious life Why then should the contacts with the sacredness of home medical service be altered?

The voices of the propagandists have been heard throughout the land Their words are the same and their thoughts identical There is a constant repetition of the need of some plan, that medicine must care for those who are sick, that doctors must be more equitably distributed, and that hospital and specialized service must be more readily accessible These futile arguments are advanced at a time when a patient can reach a physician's office or have the physician come to his home more quickly than at any time in the history of this country

I cannot agree with those who say that it is better to go somewhere than to stand still I cannot see the logic of a program which is not based on the economic satisfaction of those who are to work under it Nor do I feel that the appointment of another committee in our already top heavy organization will assist in any material way to solve the national economic riddle or the problems connected with the practice of medicine which are as all broad minded observers agree, mainly dependent upon unemployment

There is no doubt in my mind that we will do more harm than good by aligning ourselves with

the forces bent upon the destruction of the present system of private practice.

I know that each of you will display your usual wisdom after acquiring a complete knowledge of the uncertainties surrounding the introduction of any change in the practice of medicine.

Regardless of any printed statement for or against the inauguration of a new system, the fact is incontrovertible that the main object of group medicine is to tie the employee to the employer.

I urge you to avoid entangling alliances and feel certain that you will not prove false to your true selves or to your constituency by accepting any resolution or procedure presented in any guise whatsoever which will change the order of the established practice until the proposed change has been thoroughly investigated and proven by actual operation to be worthy of your acceptance.

Let us constantly guard against the insidious ingrowth of socialized service of any type. Let us scrutinize every group insurance and hospitalization scheme so as to be convinced that the patient's welfare is protected and that the sick of our State are not subjected to exploitation. Incidentally do not forget that as a result of the national government's extension and too expansive private hospital construction so unfortunately advanced by propagandists, the medical profession may be further victimized.

Whenever you come in contact with those who are advocating a new system, I suggest that you inquire into the personal relationship of the proponent to the proposed measure to the end that you may see why he is trying to foist a method of unsatisfactory, unknown, unreliable medical service upon the unsuspecting and gullible public.

Very few physicians would be content to mechanically dole out pills and mechanically give advice and even more mechanically live the life of a hired servant. There is something more noble, more exalted, more satisfying and more worthy of the true physician than just the mere serving of time for a pittance.

May the experience of the ages be with you in your deliberations.

The State Society has too many committees. They are too loosely connected to the parent organization, usurp too many functions, publish too many opinions which have not been passed upon by the legislative bodies of the Society and are, I believe, tending to retard our natural progress, for no emergency is sufficiently acute to require an immediate decision by one man or one committee.

I believe that there should be a change in the personnel of all the committees of this Society by the infusion of new blood; that is, one of the older members of the committee should be displaced by a new one. In this way we will be educating the younger men in the Society to take their part in its trained interest. I, therefore recommend to the House of Delegates that they pass a resolution to this effect.

Gentlemen of the House, I believe it should be clearly stated by you that no member of a committee should be permitted to address any organization on a subject under consideration by his committee without the consent of the Executive Committee.

The reports of the officers of the Society evidence careful, efficient, and constructive management. I wish particularly to stress the change

in appearance of the STATE JOURNAL and trust that during the next year even greater advance will be made to the end that the views of our State organization and its members will be clearly expressed.

I further suggest that each delegate act as a direct personal inspiration to his County Society in stimulating a greater interest in the JOURNAL. That a digest of the County Society activities be sent to the editor, that any gross infringement of law be reported, and that in every way the County Society be impressed with the necessity of maintaining a superior journal.

All of the members of our Society should work harder in their chosen profession to accept the new discoveries that are proven worthwhile, to discard old methods which have ceased to fulfill their expectations and to give the public the benefit of their constant study and experience.

When I hear so much about the old-fashioned general practitioner, I am chagrined, for there is not a member of this Society who would like to be classed in the group of men who did wonderfully well with the knowledge of fifty years ago, but who would now be considered woefully incompetent. And, gentlemen, do not forget that the propagandist wishes to have you laud the old-fashioned family practitioner so that after you have raised him on a high pedestal, the column may be smashed and the idol crumble in the dust and from that dust the destroyers wish to have socialized medicine arise.

Now, Gentlemen of the House, I ask your wholehearted support to the end that our State Society may assume a larger rôle in the protection of the health of the people of the state.

THE SPEAKER: Referred to Reference Committee on the Report of the President.

New Business:

THE SPEAKER: We will now proceed to New Business. Is there anything before the House?

6. OSTEOPATHY

Section 57

DR. VAN ETEN, of Bronx: WHEREAS, Osteopathy is a system of treating disease wherein drugs are not used, and

WHEREAS, in the training of osteopaths in the State of New York, the use, nature, and action of drugs is not taught, and

WHEREAS, there is a Bill, Assembly Int. 2118, print 2443, which has passed both Houses of the State Legislature and is now before the Governor, therefore, be it

RESOLVED, that the House of Delegates of the Medical Society of the State of New York, hereby express its concern for the public welfare, should this Bill become a law, and be it further

RESOLVED, that this House of Delegates communicate its concern to His Excellency, the Governor, and inform him of the dangers of permitting unqualified men, who have not the educational requirements established by the regents of the State of New York for those who prescribe drugs and, therefore, respectfully request the Governor to veto this bill in the interest of the public.

THE SPEAKER: Referred to Reference Committee on Report of the Committee on Legislation.

7. MALPRACTICE DEFENSE AND GROUP INSURANCE

Section 37

DR. HEYD, of New York: Except for some

small recessions in the years 1925, 1926, and 1931, the cost of malpractice indemnity and defense in New York State has steadily increased since the close of the war. There are probably numerous factors responsible for the rise in cost, some of which, such as the tendency of juries to award larger and larger verdicts, lie beyond the power of the Society and its members to control. Other factors, however, are to a large extent controllable and it is to these that the members of this organization must direct their energetic attention if continually increasing insurance rates are to be prevented.

It is of first importance that members have in mind the fact that every dollar paid out for malpractice suits and claims in this State comes from funds supplied by the members and which the members are required to replace. Thus a suit against any individual member is a suit against all members and each suit filed should be so regarded.

Malpractice insurance rates cannot be reduced, in fact it appears certain that they cannot be held at their present level unless both the number and cost of suits and claims can be reduced.

WHEREAS, it is apparent that the incidence of malpractice is constantly rising for the members of the Medical Society of the State of New York, and

WHEREAS the cost of malpractice actions must be met by the premiums and membership dues paid by the members, and

WHEREAS, the present trend of malpractice actions render it highly probable that the basic rate for malpractice insurance shall have to be increased, and

WHEREAS, malpractice cases are largely the result of too free suggestions by physicians, by critical and careless remarks by consulting physicians to patients therefore, be it

RESOLVED, that it shall be the policy of the Medical Society of the State of New York

(1) That no member shall give any opinion on the diagnosis made or treatment given by any other doctor, whether a member of the Society, or not, until he has accurately informed himself as to the exact circumstances as they existed at the time the diagnosis was made or the treatment given and then only when statements which may be considered as disparagement of others, are necessary to the proper care and information of the patient

(2) That members shall be ready at all times to render every proper assistance in the defense of suits and claims against other members

(3) That all members shall, whenever possible, use their best influence to discourage or prevent suits or claims against members except where in their best judgment such suits or claims are founded in fact upon injury to patients caused by clear negligence.

(4) That no member of this Society shall make a charge or receive any compensation for his services based upon the outcome of any malpractice suit or claim in which he shall appear as witness

(5) That the House of Delegates empower the President to appoint a Committee for the express purpose of devising ways and means of counteracting the number of malpractice suits against members of the Society

(6) It is suggested that the Committee consider the setting up of a special malpractice counsel group in each County Society for the following purposes

(a) To interview doctors, members of the local County Society, who are actually or potentially engaged in any malpractice suits either for the plaintiff or defendant

(b) To determine the animus and reasons why the said member is in litigation and seek to promulgate and recreate high professional standards of honor and integrity in regard to colleagues in the Society

THE SPEAKER Referred to Reference Committee on New Business A

8 FEDERAL COMPENSATION BUREAU—CHOICE OF PHYSICIANS

Section 53

DR HEYD, of New York. WHEREAS, the procedures established by the Federal Works Administration are inimical to the best interests of the doctor as the Federal Compensation Bureau have refused any form of free choice of physicians

WHEREAS, the doctors are citizens as other members of the community they should not be discriminated against in the matter of their professional work, be it

RESOLVED, therefore, that the House of Delegates instruct its Delegates to the American Medical Association to present the views of this House to the American Medical Association so that there may be established a united policy which will justly and adequately protect the physician

THE SPEAKER Referred to Reference Committee on New Business B

9 WORKMEN'S COMPENSATION ARBITRATION BUREAU

Section 42

DR HEYD, of New York. WHEREAS, each constituent County Medical Society of the Medical Society of the State of New York sets up a different procedure for the adjudication of cases that come under the Workmen's Compensation Act, and

WHEREAS, it is apparent that each County cannot afford the necessary expenses incident to the creation of an arbitration tribunal, and

WHEREAS, it is highly important that the Medical Society of the State of New York should sponsor and further the idea of arbitration in cases of dispute under the Workmen's Compensation Act, be it

RESOLVED, that the House of Delegates instruct the Executive Committee to set up a Bureau of Compensation Arbitration for the State of New York with regional branches, and further to allocate the costs of the service

To create thereby the precedent of the Medical Society of the State of New York handling Workmen's Compensation Insurance problems

THE SPEAKER Referred to Reference Committee on New Business C

10 AMENDMENT TO BY-LAWS

DR HEYD, of New York. Amend the By Laws, Chapter II, Section 1, seventh line, by deleting the words "With voice but without vote"

THE SPEAKER The amendment will lie over for one year

11 COMMITTEE ON LEGISLATION MEETINGS EVERY OTHER WEEK

Section 60

DR DOUGHERTY, of New York. In order that the legislative work of the Society may receive

proper consideration and supervision and not be left to the judgment of a single individual, no matter how competent, the Secretary recommends that the Committee on Legislation be instructed to meet every other week during the session of the Legislature and as often in addition as its Chairman may deem necessary.

THE SPEAKER: Referred to Reference Committee on Report of the Committee on Legislation.

12. LOCATIONS FOR DOCTORS BEGINNING PRACTICE

Section 34

DR. PODVIN, of Bronx: WHEREAS, the officers of County Societies are often called upon to assist doctors in the matter of selecting a place to begin practice, or those desiring to make a change in their present location, and

WHEREAS, it is impossible for the County Societies to furnish such information to their members, be it

RESOLVED, that a special Committee be appointed to secure any available information possible, for this purpose, and be it further

RESOLVED, that a report of said Committee be published from time to time in the STATE JOURNAL.

THE SPEAKER: Referred to the Reference Committee on New Business A.

13. REMITTING OF DUES

Section 50

DR. PODVIN, of Bronx: WHEREAS, it is the practice of County Societies to continue on their roll of membership certain members who are financially unable to pay the regular dues, and

WHEREAS, it is required that the local society remit the amount of ten dollars for each such member to the State Society, and

WHEREAS, this causes a severe strain on the finances of the County Society, be it

RESOLVED, that on the certification of the President and Treasurer of a County Society the State dues for such member be remitted, and be it further

RESOLVED, that the number of members thus excused from paying dues shall not exceed five per cent of the number of members in good standing of said County Society, and be it further

RESOLVED, that each member whose dues are thus remitted shall sign an agreement to pay back to the State Society the amount due as soon as he is in funds.

THE SPEAKER: Referred to Reference Committee on New Business B.

14. SOCIETY OFFICES

Section 41

DR. PODVIN, of Bronx: WHEREAS, the offices of the State Society in New York City are in a very inaccessible location, and

WHEREAS, the journey to said offices either for out-of-town members or those living within the city of New York is thus made unnecessarily tedious, be it

RESOLVED, that the Board of Trustees or Council be requested to secure a more central location for the State offices at the expiration of the present lease.

THE SPEAKER: Referred to Reference Committee on New Business C.

15. X-RAY LABORATORIES

Section 46

DR. PODVIN, of Bronx: WHEREAS, the making of a diagnosis by means of the x-rays and/or the administration of x-rays, radium or other radiant energy for treatment, or methods of diagnostic or therapeutic medical practice, and

WHEREAS, the Medical Practice Act makes the diagnosing and/or treatment of disease unlawful for anyone not duly licensed to practice medicine, and

WHEREAS, during the past ten years or more lay persons and lay organizations have established and are conducting x-ray laboratories in which lay persons are examining and/or treating patients by means of x-rays, and

WHEREAS, such lay persons are not properly qualified and are not subject to effective supervision or control, and

WHEREAS, the x-rays in the hands of inexperienced and/or irresponsible persons are in themselves a potential source of injury to the patient, and

WHEREAS, in addition to these dangers x-ray diagnosis frequently requires the administration of potent drugs or chemicals which may be legally administered only by licensed physicians, and

WHEREAS, under these conditions the lay x-ray operator and the commercial x-ray laboratories constitute a menace to the public and in addition are strictly commercial enterprises conducted by business getters who are actuated by the profit motive and who consequently do not feel themselves bound by the rules of medical ethics, but who resort to all sorts of questionable methods to attract a complaisant clientele, and

WHEREAS, by the employment of solicitors, runners and/or other business agents and by the promise of rebates or of favorable or dishonest diagnoses, obtain the patronage of unscrupulous physicians or of business and industrial organizations to the detriment of the patient, and

WHEREAS, because of their illegal activities and the desire for profit they have been unable to attract competent physicians adequately trained in radiology and as a result employ the services of individuals whose education, training, and character are unacceptable to right thinking members of the medical profession or to the American Medical Association, and

WHEREAS, the technical diagnostic and therapeutic advances being made in radiology are due to, and dependent upon, properly trained physicians to whom science must look for further progress in the field of Radiology, and

WHEREAS, the lay x-ray technicians and laboratories have so encroached upon the practice of radiology that competent and ethical medical practitioners find it more and more unattractive as a field of endeavor, thus endangering the progress and advancement of the science of radiology and the welfare of the public, be it therefore

RESOLVED, that the House of Delegates in convention assembled believes that the practice of Radiology whether for diagnostic or therapeutic purposes, constitutes in fact the practice of medicine; and, be it further

RESOLVED, that the properly constituted authorities be called upon to take the requisite steps to bar all persons not licensed to practice medicine in the State of New York from the practice of radiology; and be it further

RESOLVED, that if it is the opinion of the Attorney-General that nonmedical technicians, practicing radiology are not violating the law under present conditions, such steps be taken to institute legislation which will include radiology in the practice of medicine and to limit diagnostic or therapeutic x-ray work to duly licensed physicians or dentists, and be it further

RESOLVED, that our delegates from New York to the American Medical Association be instructed to bring their matter to the attention of the House of Delegates of the American Medical Association at the impending session

THE SPEAKER Referred to Reference Committee on New Business C

16 MEMBER IN GOOD STANDING

Section 33

DR JOACHIM, of Kings WHEREAS, the definition of member in good standing is surrounded by some doubt insofar as it applies to the benefits derived by membership in the Society in the group liability insurance, therefore, be it

RESOLVED, that the phrase 'in good standing' be more accurately defined by the House of Delegates

THE SPEAKER Referred to Reference Committee on New Business A.

17 BROADCASTING

Section 48

DR WIGHTMAN, of New York WHEREAS, the various Broadcasting Stations are being used by some drug and patent medicine manufacturers to exploit and make exaggerated and false claims for their products to the serious danger of public health, be it

RESOLVED, that the Medical Society of the State of New York go on record as favoring a Central National Clearing Bureau of the medical profession which shall act as a reference committee to confer and advise the Broadcasting Systems in accepting questionable material

THE SPEAKER Referred to Reference Committee on New Business B

18 ALCOHOL CONTROL

Section 43

DR MACVAY, of Monroe WHEREAS, the Constitution of the Medical Society of the State of New York clearly sets forth the purpose of the Society, 'to secure the enforcement of just medical laws, to enlighten and direct public opinion in regard to the great problems of medicine'

WHEREAS, the Alcoholic Beverage Control Law, delegating to respective County Medical Societies the responsibility of nominations of local commissions, assigns to the Society an action that is not concerned with a great medical problem and is outside of the proper field of activity of the Society,

WHEREAS, with the probable repeal of the Eighteenth Amendment, the County Societies will have their duties extended in this field,

WHEREAS, the further discharge of such duties will tend to jeopardize the honorable professional standing which the Medical Society of the County of Monroe has sustained in its other activities, it is therefore

MOVED, that the Medical Society of the County of Monroe take a definite stand in regard to

its activities in this politico-social problem, it is further

MOVED, that this society go on record as being opposed to further functioning in this field of activity, and it is further

MOVED, that this action be transmitted to the Medical Society of the State of New York both by our delegates at the next annual meeting and in any other way that the Comitia Minora sees fit

THE SPEAKER Referred to Reference Committee on New Business C

19 POOLING RESOURCES OF PERSONS WITH LIMITED EARNING CAPACITY

Section 52

DR. FERBER, of New York WHEREAS a Committee appointed by the House of Delegates of the State Medical Society of Michigan, in September, 1931, in its report rendered July, 1933, shows that 92 per cent of the people receive but 65 per cent of the total annual income of the population and

WHEREAS, this same Committee in a study of the living costs of this 92 per cent of the population, found that it ranged from \$42.00 below to \$443.00 above the family income, and

WHEREAS, this Committee also reports that whenever income was found in excess of living costs, it was also shown that medical care must compete with insurance, transportation, education and inner urges that draw on the reserve that remains over the living expenses, and medical care is always the weakest, least considered competitor, and

WHEREAS, the statistics of the United Hospital Fund in New York show a constant and alarming increase in the attendance in the free dispensaries—the total number of individuals treated in the dispensaries in 1920 being 927,421 whereas in 1932 about 2,500,000 individuals were given free treatment by the doctors in the dispensaries with a total number of 7,623,765 treatments, and

WHEREAS, this alarming increase in the free treatments by physicians was constant and progressive even before and therefore not mainly caused by the depression, and

WHEREAS, this increasing burden of medical charity added to the constantly declining income of the doctor very seriously threatens his economic position, therefore, be it

RESOLVED, that a Committee be appointed by the properly constituted authority of our State Society for the purpose of devising some plan whereby people with limited earning capacity can pool their resources in order to have funds available to pay for their medical care this Committee is to report to the House of Delegates at the next Annual Meeting

THE SPEAKER Referred to Reference Committee on New Business B

20 SCHOOL VACATION

Section 45

DR. BUCKMASTER of Chautauqua WHEREAS, the school year in the State does not end until the latter part of June allowing only July and August for vacation for the children, and

WHEREAS, the Chautauqua County Medical Society did go on record in favoring a shortening of the vacations throughout the school year, that school might be dismissed earlier in June, be it

RESOLVED, that the Medical Society of the State of New York recommend that the State Department of Education close the public schools of the State not later than the middle of June.

THE SPEAKER: Referred to Reference Committee on New Business C.

21. LABORATORIES OF CLINICAL PATHOLOGY Section 36

DR. BOETTIGER, of Queens: WHEREAS, in the conduct of Laboratories of Clinical Pathology, operated to assist the physicians in the diagnosis of disease, interpretation of findings is required, and

WHEREAS, such interpretation requires clinical knowledge and experience, therefore be it

RESOLVED, that the conduct of such laboratories is properly one of the specialties of the practice of medicine and that directors of such laboratories should be physicians licensed to practice medicine.

THE SPEAKER: Referred to Reference Committee on New Business A.

22. CONTRACT MEDICAL CARE Section 51

DR. BOETTIGER, of Queens: WHEREAS, the principles of professional conduct established by the Society are/or may be implicated and compromised in plans to provide cheap or "contract" medical care, therefore, be it

RESOLVED, that we reaffirm our position in these words:

It shall be considered unethical and unbecoming a gentleman and a physician to participate or engage in any plan, scheme or program, or institutional activity for the provisions of medical care through any agency which commercializes such care by solicitation in the form of printed, written, or spoken advertisement distributed or displayed to or through lay or nonmedical channels.

And further, the self-appraisal by laudatory claims of unusual or superior character or facility of service, or the setting up by an institution or plan of a schedule of "cut-rate" fees for medical or surgical care, shall be considered to be the acts of each individual employed or engaged therein, and for which conduct he shall be held accountable to and subject to discipline by the County Medical Society.

THE SPEAKER: Referred to Reference Committee on New Business B.

THE SPEAKER: Dr. Farmer will now present a supplementary report of the Committee on Public Health and Medical Education.

22 A. SUPPLEMENTARY REPORT Section 39-65

COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

Subsequent to the submission of the regular report of this Committee several important matters have come to its attention which have required its consideration. At a recent meeting of the Committee it was decided that a supplementary report, covering these subjects, should be submitted.

Diphtheria Immunization

The State Department of Health is carrying on at the present time a campaign for immunization of children against diphtheria. The various agencies which operated in the five-year

campaign some years ago are participating in this campaign. This campaign was started because outbreaks of diphtheria were more prevalent in the State in 1933 than in 1932. The increase, while not alarming, did seem to justify some action that would prevent a corresponding increase in 1934. Your Committee on Public Health and Medical Education has sent a letter to the Secretaries and the Chairmen of the Public Health Committees of all county medical societies informing them of the purposes and plan of this campaign. Each county society has been asked to bring this matter to the attention of the physicians in their society and to develop a program which will include a definite plan providing for this work to be done as much as possible by the individual physician and also cooperation with the State Department of Health whereby children in all families will be immunized. Your Committee believes that it is essential that all children should be immunized against diphtheria. However, it calls attention to the fact that in accomplishing such results the province of the official department of health should be the advertising of the necessity of such immunization while the actual work of immunization should be the province of the physician. Such a policy requires the county medical society to effect a proper organization for that purpose.

Standing Orders for Public Health Nurses

Your Committee has received from the Division of Public Health Nursing of the State Department of Health a list of suggestive standing orders for public health nurses. These orders cover the usual daily routine work of the nurse, first-aid work, and temporary use before the nurse has contacted the attending physician. A subcommittee which has been appointed to study these suggestions has not had sufficient time to make its report. If after doing so it is deemed necessary and proper these suggestions will be sent to the various county medical societies for their approval.

Nursing Education in New York State with Suggested Remedial Measures

The attention of your Committee has been very recently called to certain suggested remedial measures dealing with nursing education which have been proposed by the State Department of Education. Your Committee believes that these suggested measures are important enough to be studied by this Society and recommends that the House of Delegates authorize the Committee on Public Health and Medical Education to make such a study and report its findings as early as possible to the Council or its Executive Committee.

Control of Syphilis

Two members of the Committee, Dr. Kosmak and the Chairman, were recently asked to take part in a conference dealing with the subject entitled, "What are the Most Important Measures in the Community Program for the Prevention of Syphilis and How Can They Promptly Be Put into Effect?" This conference was arranged by the Committee on Tuberculosis and Public Health of the State Charities Aid Association. Although the subject of the conference referred to a Community Program, nevertheless, the discussions included to a large degree the treatment of syphilis and indicated the tendency in certain groups for this treatment to be carried on only

by specialists or that complete responsibility for treatment be given to the government. While it was agreed beforehand that the conference should adopt no definite conclusions, nevertheless, there was considerable expression of opinion disagreeing with these two above mentioned contentions. The members of your Committee contended that diagnosis and treatment of syphilis was a medical problem, belonged in the hands of the physician, and that the medical profession was carrying on the adequate educational work to provide proper treatment. Your Committee believes that this should be brought to your attention in order to inform you of these tendencies and also of the necessity of continual graduate education in the treatment of syphilis. This conference also considered the advisability of requiring a blood test for syphilis in all pregnant women the same as prophylactic measures are required for the prevention of ophthalmia neonatorum. One health official questioned the legality of such requirement. The members of your Committee felt there was a growing tendency on the part of physicians to have blood tests on such cases and that continued improvement would be better accomplished through education rather than regulation.

County Maternal Welfare Commissions

In its regular report the Committee has recommended the organization in each county medical society of a maternal welfare commission. At its last meeting Dr Arthur W Bingham who organized the first commission in the Essex County Medical Society of New Jersey, addressed the Committee describing the work in the State of New Jersey and what had been accomplished. Your Committee is more convinced than ever that while such commissions should be established and organized by members of county medical societies, they should request and welcome the cooperation of all other organizations organized for this purpose. Dr Bingham's report shows that this cooperation has been obtained in New Jersey but that the direction of the work has been definitely under the control of the Commission of the County Medical Society.

General Comment

The matters contained within the regular as well as this supplementary report of this Committee demonstrate the vital need of wide awake efficient public health committees in each county medical society. The President of each county society should see that such committees are immediately appointed and their names reported to your State Committee. The Presidents of the District Branches might be charged with the responsibility of seeing that this is done in each District. With the proper organization of such committees your State Committee can make considerable progress in dealing with the various subjects of the report during the coming year.

THE SPEAKER This supplementary report will be referred with the original report to the Reference Committee on Public Health and Education.

23 UNETHICAL MEDICAL ADVERTISING OVER THE AIR

Section 49

DR. SAYL, of New York. WHEREAS, it has become increasingly apparent to members of the Society that advertising over the air has become increasingly more unethical, and

WHEREAS, the County Medical Societies in the metropolitan district have through their various committees, succeeded in obtaining only a moderate degree of cooperation with the radio broadcasting stations with a view of causing a cessation of unethical medical advertising over the air, and

WHEREAS, the broadcasting stations are calling upon organized medicine for support in the arrangement of sustaining programs, and

WHEREAS, organized medicine and members of the medical profession have cooperated with the broadcasting stations to provide informative medical programs of interest to the public and in the interest of the public health over the air, and

WHEREAS the American Medical Association has made arrangements with national broadcasting organizations to provide such sustaining programs for them from the headquarters of the American Medical Association in Chicago, therefore, be it

RESOLVED that the delegates from the Medical Society of the State of New York to the House of Delegates of the American Medical Association bring to the attention of the House at the impending session in Cleveland the fact that organized medicine and the medical profession are dissatisfied with the quality of commercial programs advertising various proprietary and household remedies, and believe that these programs are of such a nature as to be inimical to the welfare of the people and detrimental to the interests of the medical profession, therefore, be it further

RESOLVED, that our delegates call upon the American Medical Association to take such steps as they may deem advisable and necessary to cause an improvement in radio broadcasting and a cessation of unethical practice as above outlined, over the air.

THE SPEAKER Referred to Reference Committee on New Business B

24 NURSE ANESTHETIST

Section 40

DR. WELKER, of New York. WHEREAS, the House of Delegates of the Medical Society of the State of New York at its last session in New York City, in April 1933, passed a resolution as to the nurse anesthetist, which resolution was referred to the properly constituted authorities of the Medical Society of the State of New York, for further action, therefore, be it

RESOLVED, that the delegates of the Medical Society of the State of New York to the American Medical Association be instructed to present a similar resolution to the House of Delegates of the American Medical Association at the impending session in Cleveland, Ohio.

THE SPEAKER Referred to Reference Committee on New Business C

25 DUES REDUCED FOR YOUNG PRACTITIONERS

Section 35

DR. KOSMAK, of New York. WHEREAS it would be in the interest of organized medicine and of the County Medical Societies to include within its membership as large a percentage of ethical practitioners of medicine as possible and

WHEREAS, the Membership Committee of the Medical Society of the County of New York is of the opinion that specific inducements should be made in the way of lightening the financial

burden of membership for medical men who are in practice less than five years and are unable to meet the full financial requirements of membership, and

WHEREAS, there is a large group of young practitioners who are eager to join the ranks of organized medicine by joining the County Medical Societies, therefore be it

RESOLVED, that the House of Delegates go on record as favoring a 50 per cent reduction in the State assessment for medical practitioners less than five years in practice, and be it further

RESOLVED, that the properly constituted authorities of the Medical Society of the State of New York take steps to initiate such changes in the Constitution and By-laws as to enable the State Society and the County Societies to accept membership on this basis.

THE SPEAKER: Referred to Reference Committee on New Business A.

26. SUPPLEMENTARY REPORT OF COMMITTEE ON LEGISLATION

Section 59

DR. ARANOW. Presented the following supplementary report:

The legislative season for 1934 finally closed on Saturday, April 28th at 2:30 A. M. Your committee never had so much legislation to concern itself with, and it is pleased to report that no inimical or undesirable legislation was passed by both Houses except the fifth osteopathy bill which, after having been defeated in the Assembly, was reconsidered and passed. Later it was passed by the Senate toward the close of one of its prolonged night sessions. At 2:00 A. M. it was voted upon after a display of much political and sentimental influence in its favor. We filed with the Governor arguments against his signing the bill and invited the County Societies to do likewise.

Permit me here to again call attention to the one great defect in our organization, the apparent lack of interest on the part of the individual physician. I have definite information that hundreds of osteopathic sympathizers have written to the legislators and the Governor while the response from the medical profession has been practically limited to the officers of the County Society.

Gentlemen of the House of Delegates, we, the members of the Medical Profession, have the greatest potential power of any group in the state, and yet because of lack of organization we allow groups to develop sufficient political influence to pass legislation inimical to the interest of the public in the medical profession.

Our hospital lien bill, which would accord the privilege of filing a lien not only to the hospitals but to the physicians and nurses, passed the Senate with no difficulty but was defeated in committee on the Assembly side because of a technicality.

The hospital dispensary and nurse anesthetist bills could not be moved from their respective committees. The chairmen of the committees and introducers of the bills claimed there was too much opposition to the bills to have them advanced. Three antivivisection, two antivaccination and two 2-per cent sales tax bills were defeated in committee. No chiropractic bill was introduced.

Several amendments to the Workmen's Compensation Law, particularly one to provide for the creation of treatment clinics throughout the State, with which we were not in sympathy, were defeated. The bill that was drafted on the report of the Governor's Special Committee on Workmen's Compensation, was discussed at a hearing before the Senate Committee on Labor and Industry and afterward amended in a way to make it very unacceptable to us. Therefore, we opposed its advancement in the amended form, with the result that it was killed in committee.

A bill aiming to put all clinical and pathological laboratories under the control of licensed physicians was introduced, but opposition to it was so powerful that it could not be advanced, in spite of the fact that an attempt was made to amend it successfully.

At a conference of the committee held subsequent to the adjournment of the Legislature for the purpose of reviewing the work of the session, it was decided that during the interim before the next Legislature convenes, new drafts of the hospital lien and clinical laboratory bills should be made in accordance with criticism and suggestions offered by the legislators. It was further agreed that special efforts must be made to arouse interest in the nurse anesthetist and hospital dispensary bills if they are to be more favorably considered by the Legislature.

Finally, let me again urge the medical profession, through the House of Delegates, to initiate the organization of lay groups throughout the State to protect the public against vicious medical legislation detrimental to the health and welfare of the people of the State of New York. The medical profession has carried this burden alone altogether too long.

THE SPEAKER: Referred to the Reference Committee on Report of the Committee on Legislation.

27. SOCIALIZATION OF MEDICINE

Section 44

DR. FRUCHT, of Kings: WHEREAS, in the report of our President of the State Society, there is immediate danger for the socialization of medicine by lay bodies, and

WHEREAS, in the *Journal of American Medical Association* an editorial on May 12th, states that there is a trend toward a change in the present form of medical practice, and

WHEREAS, a large group of physicians in New York City have already formulated a plan, be it

RESOLVED, that the Committee on Economics investigate the plans proposed and report at the next session of the House of Delegates.

THE SPEAKER: Referred to Reference Committee on New Business C.

28. PUTNAM COUNTY MEDICAL SOCIETY

Section 32

THE SPEAKER: This, gentlemen, is a petition for the formation of a Putnam County Medical Society.

"We, the undersigned physicians, members of the Dutchess-Putnam County Medical Society and residents of Putnam County, do hereby petition the House of Delegates of the Medical Society of the State of New York for permission

to form our own separate organization, to be known as the Putnam County Medical Society'

E Roberts Richu, Brewster
George H Stacey, Lake Mahopac
Alexander Vanderburgh, Brewster
Robert S Clazer, Brewster
Frank C Genovese, Patterson
Ralph M Hall, Cold Spring
W J Cowan, Cold Spring
Corryell Clark, Cold Spring
Francis J McKaun, Carmel
John T Jenkins, Lake Mahopac

We, the undersigned physicians practicing in Putnam County, do hereby petition the House of Delegates of the Medical Society of the State of New York for permission to organize a Putnam County Medical Society

Garrett W Puk, Carmel
William P Kelly, Carmel
W P Locke, Cold Spring

THE SPEAKER Referred to Reference Committee on New Business C

29 SUPPLEMENTARY REPORT, COMMITTEE ON ECONOMICS Section 71

DR GOODRICH, of Kings Since the report of the Committee on Economics was written and handed to the printer, the chairman of the Economics Committee at the expenditure of a large amount of time and skill and general ability, has had made for the information of the House of Delegates a large chart which shows all of the paragraphs in the various laws of the State of New York which have to do with the care of the indigent It shows how these are related, how they conflict, how they are sometimes inconsistent and in some ways how they need codification

This is the first large step the preparation of these paragraphs and bringing them together, the first step in the work that is mentioned in the report of the Committee on Economics, which shows that we are endeavoring to cooperate with all of the State departments in investigating the laws concerning the care of the indigent and in assisting and cooperation in their codification

THE SPEAKER Referred to Reference Committee on Report of Committee on Economics

30 RACIAL DISCRIMINATION

Section 70

DR. LEITNER, of Rockland WHEREAS civilized peoples have never discriminated against anyone who contributes to medical science or against one who is qualified to engage in the healing of the sick because of his race, or religious belief, or economic views,

WHEREAS, under the Nazi regime, by governmental decrees and otherwise persons engaged in research or the practice of medicine have been either barred or expelled from their laboratories and clinics without justice or reason, other than that they differed in racial origin or religion from that of their colleagues, and

WHEREAS, our brother physicians are not permitted to participate in the health insurance service and are permitted to consult only with physicians designated by the German Government, and expelled from medical societies and clubs in spite of their previous noteworthy contribution to science and medicine and

WHEREAS, such discrimination tends to hamper

the efforts of the profession in its chosen task of combating disease and alleviating suffering, and

WHEREAS, German medicine, previous to the past year, has made outstanding contributions in the field of human progress,

WHEREAS, the measures instituted by the present Nazi government are doing incalculable harm to the progress of medicine throughout the world, therefore, be it

RESOLVED, that the Medical Society of the State of New York record its abhorrence and voice its resentment against such practices as being unfair inhuman, and inimical to progress of medicine generally and a violation of those humane ideals which are amongst the cherished traditions of the medical profession and be it further

RESOLVED, that the Delegates of this House to the American Medical Association be instructed to register the protest of this body

THE SPEAKER This resolution will be referred to the Reference Committee on New Business A

THE SPEAKER There being no further resolutions, I declare a recess while the Reference Committees organize The House will reconvene at 2 30 P M

AFTERNOON SESSION, 2 30 P M

The meeting was called to order by the Speaker at 2 30 P M

31 WOMEN'S AUXILIARY

DR FLAHERTY Mr Speaker, last year at the meeting of the House of Delegates, a motion was passed that we were in favor of establishing a women's auxiliary of the Medical Society of the State of New York We have with us to day the wife of Dr Robert Tomlinson, Mrs Tomlinson, of Wilmington Delaware, who came up here purposely to tell us of the ideas and purposes of the Women's auxiliary

THE SPEAKER Mrs Tomlinson has the floor
MRS TOMLINSON I will take office in Cleveland as the next president of the Women's Auxiliary to the American Medical Association

The membership of the auxiliary is confined to the immediate women members of physicians' families and is largely composed of the wives of physicians

It is organized in thirty eight or thirty nine states and the District of Columbia in this country and elsewhere and has some fourteen thousand members

In beginning any auxiliary that is formed, it must have an advisory council, usually of three to five members of the State Medical Society, because there is no work which an auxiliary may undertake which has not been approved by this advisory committee

We believe that we can be useful and I believe in most Medical Societies that the auxiliaries have proven useful

We meet with other physicians' wives, we can talk about affairs that are of interest to the public, we can keep our ears to the ground While we may not tell anything about treating the sick—that is not our province—we can try and put hygiene in the schools, we can meet with the Parent-Teachers Associations and we can help sometimes with legislation if you ask us to do it We cannot do it otherwise We can talk

preventive medicine which covers such a large field now. We can make reports on public health to women's organizations.

If in the State of New York you want an auxiliary, the first thing is to have your council of the men whom your president will appoint. If, after they are appointed, they wish us to do it, we will be more than glad to communicate with the presidents of your various county medical societies, asking them to appoint one woman to organize that county, or perhaps to call a group of the women together to organize it.

If you wish it, we would be glad to help with that organization, to speak to your wives of the use that we believe that they—organized—can be to you.

32. PUTNAM COUNTY MEDICAL SOCIETY

Section 28

THE SPEAKER: Is there any reference committee ready to report?

DR. PODVIN, of Bronx: Reference Committee on New Business A. Relative to the petition for the formation of a Putnam County Society, it is the opinion of the Committee that this petition should be referred back to the Dutchess-Putnam Society for a conference between them.

The result of this conference to be reported to the House of Delegates for final action.

I move its adoption.

Motion seconded and carried.

33. MEMBER IN GOOD STANDING

Section 16

In reference to the Resolution presented by Dr. Joachim, requesting the definition of the phrase "good standing," your Committee recommends the adoption of this Resolution with a change, whereby the matter is referred to the Council.

The Resolution reads, as follows:

WHEREAS, the definition of "member in good standing" is surrounded by some doubt insofar as it applies to the benefits derived by membership in the Society in the group liability insurance, therefore, be it

RESOLVED, that the phrase "in good standing" be referred to the Council of this Society for the purpose of securing a ruling that will accurately define this phrase; or if necessary the proposal of amendments to the by-laws for this purpose.

I move its adoption.

Motion seconded and carried.

34. LOCATIONS FOR DOCTORS BEGINNING PRACTICE

Section 12

Your Reference Committee approves of the subject matter in the resolution submitted by Bronx County in regard to assisting doctors in the matter of selecting places to begin practice but believes that the necessary information can better be secured by the Executive Officer than by any Special Committee and therefore presents the following amended resolution:

WHEREAS, the Officers of County Societies are often called upon to assist doctors in the matter of selecting a place to begin practice, or those desiring to make a change in their present location, and

WHEREAS, it is impossible for the County Societies to furnish such information to their members, be it

RESOLVED, that we recommend to the properly constituted authorities that the Executive Officer be directed to secure and keep available information for this purpose.

I move its adoption.

Motion seconded.

DR. BEDELL: May I ask a question? Why should it be the Executive Officer instead of our secretarial officer?

DR. PODVIN: We felt that the Executive Officer was more in touch with conditions throughout the state. He goes around more and would be in a better position to get this information together.

Motion carried.

35. DUES REDUCED FOR YOUNG PRACTITIONERS

Section 25

DR. PODVIN, of Bronx: In reference to the resolution in regard to reduced membership fees for young practitioners, your committee approves of this resolution with a slight change of wording to clarify the meaning.

The resolution now reads as follows:

WHEREAS, it would be in the interest of organized medicine and of the County Medical Societies to include within its membership as large a percentage of ethical practitioners of medicine as possible, and

WHEREAS, the Membership Committee of the Medical Society of the County of New York is of the opinion that specific inducements should be made in the way of lightening the financial burden of membership for medical men who are in practice less than five years and are unable to meet the full financial requirements of membership, and

WHEREAS, there is a large group of young practitioners who are eager to join the ranks of organized medicine by joining the County Medical Societies, therefore, be it

RESOLVED, that the House of Delegates go on record as favoring a fifty per cent reduction in the State assessment for physicians for the first five years after graduation from Medical College, and be it further

RESOLVED, that the properly constituted authorities of the Medical Society of the State of New York take steps to initiate such changes in the constitution and by-laws as to enable the State Society and the County Societies to accept membership on this basis.

I move its adoption.

Seconded.

THE SECRETARY: I don't see just what we are going to do about legal defense in malpractice cases if we reduce the dues for anybody here.

DR. KOSMAK, of New York: I fully realize the condition which has been presented by Dr. Dougherty. It might be practical to add as an amendment to this resolution that malpractice defense should not be included for these men who pay reduced fees.

The primary object, gentlemen, in proposing this was to get as many of the younger men interested in the organized medical profession as possible, and I think that if you hold out some such inducement as this you will get in a great many men who would otherwise remain outside the ranks.

I think it is a matter that should be very carefully considered by this House of Delegates.

I don't believe that the men who have recently

graduated will be interested in the question of malpractice insurance.

Therefore I think we should hold out this inducement possibly with the amendment that malpractice defense be excluded.

THE SPEAKER: Will you present an amendment, Dr. Kosmak?

DR. KOSMAK: I would like to present that in the form of an amendment:

RESOLVED, that the malpractice defense clause be not included in this class of membership.

DR. SCHIFF, of Clinton: It would seem to me unnecessary to propose such an amendment. In a group of practitioners under five years, owing to the number of cases that such practitioners will have, the liability of malpractice must of necessity be considerably smaller and it would seem to me that that proportion of dues would carry its own share of defense.

Personally I believe that this type of inducement to get men interested in organized medicine early in their medical careers is worth while.

DR. GROAT, of Onondaga: I move an amendment that that part of the resolution which refers to the elimination of defense against malpractice be stricken out.

Motion seconded.

THE SPEAKER: Are you ready for a vote on the last amendment: "Resolved, that the malpractice defense clause be not included for this class of membership, namely those who only pay fifty per cent to the state assessment, who are five years out of medical college." That is the amendment made by Dr. Groat, that that be deleted and have no part in the proposal as it will come before you if you vote on this amendment.

A vote was thereupon taken.

THE SPEAKER: The chair is in doubt. Those in favor kindly rise.

The amendment is carried.

THE SPEAKER: Now we have to vote on the proposition as amended. The resolution reads: "That the House of Delegates go on record as favoring a fifty per cent reduction in the state assessment for physicians for the first five years after graduation from medical college, and be it further

RESOLVED, that the properly constituted authorities of the Medical Society of the State of New York take steps to initiate such changes in the Constitution and By-laws as to enable the State Society and the County Societies to accept membership on this basis.

THE SECRETARY: On a point of order. My point of order is that that resolution is absolutely wrong in its wording because we have no such clauses in the By-laws or Constitution.

We must remember that there are any number of activities of this Society that are not in the Constitution or By-laws. Our society is run by resolution more than by Constitution or By-laws. The resolutions of the House hold until the meeting of the next House. Anything you put in your By-laws has to lie over for a year for action by the House of Delegates.

If you look at your By-laws you won't find anything that says you shall have a Counsel; it does not say anything about the fact that you must have a JOURNAL; it does not say anything about dues; there are any number of things of that kind, and I noticed some of the resolutions this morning that were a little contradictory.

THE SPEAKER: The point of order is well taken. The last paragraph of the resolution is

not necessary because it conflicts with nothing. Those in favor of the resolution: "That the House of Delegates go on record as favoring a fifty per cent reduction in the state assessment for physicians for the first five years after graduation from medical college."

A vote was taken.

THE SPEAKER: The chair is in doubt. Those in favor kindly rise. * * * Those against kindly rise. * * * The motion is lost.

36. LABORATORIES OF CLINICAL PATHOLOGY

Section 21

DR. PODVIN, of Bronx: Reference Committee on New Business A. With reference to the resolution:

"WHEREAS, in the conduct of laboratories of clinical pathology operated to assist the physicians in the diagnosis of disease, interpretation of findings is required, and

"WHEREAS, such interpretation requires clinical knowledge and experience, therefore, be it

"RESOLVED, that the conduct of such laboratories is properly one of the specialties of the practice of medicine and that directors of such laboratories should be physicians licensed to practice medicine."

Your Reference Committee approves this resolution and moves its adoption.

Motion seconded.

DR. KNICKERBOCKER, of Ontario: There are established throughout the state numerous laboratories, some of which are under the charge of men who are not M.D's. They are competent and capable men, approved by the State Society. Does this resolution affect them?

DR. PODVIN: I should say under this resolution it does. The wording of it is "that the conduct of such laboratories is properly one of the specialties of the practice of medicine and that directors of such laboratories should be physicians licensed to practice medicine." I don't think it could be made any clearer. Perhaps Dr. Boettiger, who introduced the resolution may wish to say a word.

DR. BOETTIGER, of Queens: The purpose of the resolution is to establish a principle. It has no reference to any law of any kind.

A vote was taken and the motion carried.

37. MALPRACTICE DEFENSE AND GROUP INSURANCE

Section 7

DR. PODVIN, of Bronx: Reference Committee on New Business A. Your Committee, after discussing the resolution submitted by Dr. Heyd finds that it would be unwise to accept Section 1, and that Sections 5 and 6 can accomplish no practicable result. We also find it advisable to clarify the preamble by inserting an additional paragraph and modifying the wording of one paragraph.

The Resolution, as amended, reads as follows: WHEREAS, it is apparent that the incidence of malpractice is constantly rising for the members of the Medical Society of the State of New York, and

WHEREAS, the cost of malpractice actions must be met by the premiums and membership dues paid by the members, and

WHEREAS, the present trend of malpractice actions render it highly probable that the basic rate for malpractice insurance shall have to be increased, and

WHEREAS, malpractice cases are often the result of critical and careless remarks by physicians to patients, and

WHEREAS, the practice of rendering expert testimony upon a contingent fee basis is in violation of Section 28 of the Principles of Professional Conduct, be it

RESOLVED, that it shall be the policy of the Medical Society of the State of New York:

(1) That all members shall, whenever possible, use their best influence to discourage or prevent suits or claims against members, except where in their best judgment such suits or claims are founded in fact upon injury to patients caused by clear negligence.

(2) That members shall be ready at all times to render every proper assistance in the defense of suits and claims against other members.

(3) That no member of this Society shall make a charge or receive any compensation for his services based upon the outcome of any malpractice suit or claim in which he shall appear as witness.

I move its adoption.

THE SPEAKER: The amended resolution of the Reference Committee is before you. Is there any discussion?

DR. LEBER, of New York: May I ask if there is any method by which this resolution will come to the attention of the rank and file of members of the State Medical Association?

THE SPEAKER: The transactions of the House of Delegates are published in the JOURNAL.

DR. LEBER, of New York: I repeat my question. I think this is one of the most important resolutions you have before you. I have thought for years that the members of the Society have been very negligent, or rather, their counsel, in not giving them the opportunity to know how to avoid malpractice suits and I think that just passing a very important resolution such as this today in the hope that some member may read it, I think, is perhaps losing the best part of the meat of that resolution.

DR. BOETTIGER, of Queens: As a member of the Reference Committee, I wish to emphasize the statement just made. We would like in some way to have this important fact very strongly brought to members of the profession.

DR. ARANOW, of Bronx: Referring to the preamble to the resolution, it seems to me an unwise thing to go down on record that we are opposed to any doctor criticising another doctor. We are opposed to criticising him unjustly, but we don't want to go on record as an organized group.

THE SPEAKER: I think a re-reading of the preamble will clear the atmosphere.

DR. PODVIN, of Bronx: The part Dr. Aranow refers to was in the preamble of the original resolution as presented by Dr. Heyd, but the resolution as amended by the committee does not contain that. It says: "Your Committee, after discussing the resolution submitted by Dr. Heyd, finds that it would be unwise to accept Section 1."

That is the section which contains that part. Then it goes on about the incidence of malpractice, which it is unnecessary for me to read again. There is no reference to expression of opinion.

DR. GOODRICH: I move you, that this motion be amended by adding these words: "And that the House of Delegates direct the Executive

Committee to make this resolution the subject of editorial comment."

THE SPEAKER: The resolution as amended is before the house.

A vote was taken and the motion carried.

38. REPORT OF THE REFERENCE COMMITTEE ON THE REPORT OF THE TREASURER AND THE BOARD OF TRUSTEES

DR. DANNREUTHER, of New York: Your Reference Committee on the Report of the Treasurer and the Board of Trustees commends all of those responsible for the financial condition of the Society, the conservation of its resources, and the stability of its investments. Your Committee endorses the Treasurer's policy of having available sufficient funds to be utilized for serious emergencies that may arise from time to time. Your Committee also approves of the yearly addition of reasonable amounts to the reserve funds of the Society. Your Treasurer submitted detailed supplementary reports of all expenditures and your Committee examined particularly the items included in the expenses of the Committee and general salaries. Your Committee is convinced that all of these expenses were necessary and justifiable. The net cost of the Directory has been reduced to a minimum. While the cost of the JOURNAL amounted to a little more than \$6,000 for the current year, the complete change in its format and editorial expenses, initiated January 1, 1934, will undoubtedly eventuate in its future conversion into a financial asset to the Society. Your Reference Committee agrees with the Board of Trustees that all expenditures should be carefully scrutinized and restricted to essentials, and that strong reserves are necessary to equip organized medicine for a possible conflict with the proponents of socialized medicine.

I move its adoption.

Motion seconded and carried.

39. REPORT OF REFERENCE COMMITTEE ON REPORT OF COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

Section 22A-65

DR. CRITCHLOW, of Erie: This Reference Committee has individually and collectively made a careful study of the report of the Committee on Public Health and Medical Education. We desire to congratulate the Society on having a committee which gives evidence in its annual report of having devoted so much time and thoughtful attention to the various problems confronting them in their particular field.

We approve of the report in its entirety, but wish to stress a few of the special topics therein discussed.

GRADUATE EDUCATION

We believe the report rightly gives first place to the subject of Graduate Education. The plan now being pursued by the committee, of sponsoring graduate courses through the County Societies, would seem to be the most practical and best calculated to accomplish the desired result, namely, arousing the interest of physicians generally in the idea of continuation studies in live medical subjects. The increasing number of counties availing themselves of this opportunity speaks for the soundness of the plan now in action. We believe the committee's idea is sound in concentrating the topics of any course on a more or less definite subject. We recommend a continuation and further development of

the committee's general plan of Graduate Education

I so move

Motion seconded and carried

GENERAL PUBLIC HEALTH ACTIVITIES

This section of the report is brief, merely mentioning tuberculosis, cancer, examination of school children by private physician. We note that a special subcommittee will report to the House of Delegates on a study of the deaf and hard-of-hearing children in the State. We await with interest the more definite report promised on the subject of arthritis as a public health question.

"The individual physician and preventive medicine," is a topic which occupies one half of the space devoted to the report under review. The importance of the subject as bearing on the economic future of the general practitioner fully justifies the prominence accorded to the question.

In these days, when the fear of State Medicine is ever present in the minds of physicians, any discussion is pertinent and timely, which considers possibilities for enlarging the field of the practitioner's activities. That the work of Health Departments is seriously encroaching on the territory of the private physician few will deny. Can this expansion of departmental activities be checked by allocating to the practitioner some of the duties now assumed by the state? This, in brief, is the question propounded in the report under review. The committee states its belief 'that this society can introduce a plan whereby the physician will participate more directly in the field of preventive medicine and briefly outlines the essential features that should be embraced in such a plan.

We heartily endorse the recommendation of the Committee that the House of Delegates take some action. We are of the opinion, however, if such action goes only so far as to urge County Medical Societies to consider a plan that valuable time would be lost. We believe more direct action is better, we therefore, recommend that the Committee on Public Health and Medical Education be instructed to formulate such a plan, for submission to the County Societies for action.

I so move

DR CONWAY, of Albany. Do you appreciate what that means? That a Committee of this House is to present a plan to the County Societies for action? Have you gone over the history of these other state societies that have gone through this same thing?

THE SECRETARY. This is absolutely wrong. No committee ought to be allowed power of this kind. The committee should, after formulating the plan, make their report according to law, to the Executive Committee.

DR. FARMER, of Onondaga. As chairman of the committee, I want to make it plain that we would submit such a plan to the Executive Committee first. I am sure the Reference Committee will make it plain that they would want that done.

DR. KAUFMAN, of New York. I move that the resolution be referred back to the committee for correction.

Motion seconded and carried.

DR CRITCHLOW, of Erie. Maternal Mortality.

We would emphasize that section of the report dealing with maternal mortality. We approve the recommendation of the committee that the House of Delegates authorize the Committee on Public

Health and Medical Education to organize Maternal Welfare Commission in each County Society and to advise in regard to their specific duties. We so recommend.

THE SPEAKER. You have heard the recommendation.

THE SECRETARY. I hope Mr. Speaker, that this will be changed. I think Dr. Farmer really means that it should come from the Committee to the Executive Committee. No standing committee has a right to do anything else on its own initiative. They must report to the Executive Committee.

DR KAUFMAN, of New York. I move that it be referred back to the committee.

Motion seconded and carried.

DR. CRITCHLOW, of Erie. At the same time we believe the Committee on Public Health and Medical Education should prepare to correlate the findings of various medical organizations that have already made or in the future may make, surveys of the maternal mortality problem. We so recommend.

We approve the recommendation of the Committee on Public Health and Medical Education in their supplementary report that the said Committee be instructed to study the suggested remedial measures on nursing education in New York State and report to the Council without delay.

Finally, we wish to express our appreciation of the services of Dr. Farmer, and his committee, in bringing briefly but forcibly to our attention the subjects treated in the report under review.

I move its adoption.

Motion seconded and carried.

40 NURSE ANESTHETIST

Section 24

DR. HAMILTON, of New York. WHEREAS the House of Delegates of the Medical Society of the State of New York at its last session in New York City in April 1933, passed a resolution as to the nurse anesthetist, which resolution was referred to the properly constituted authorities of the Medical Society of the State of New York for further action, therefore, be it

RESOLVED, that the Delegates of the Medical Society of the State of New York to the American Medical Association be instructed to present a similar resolution to the House of Delegates of the American Medical Association at the impending session in Cleveland, Ohio.

The Committee on New Business C recommends the approval of the resolution introduced by the Medical Society of the County of New York in reference to the Nurse Anesthetist as to the instruction of the delegates to the meeting of the American Medical Association, in Cleveland, Ohio.

I move its adoption. Motion seconded.

DR. ROONEY, of Albany. May we have the original resolution read?

The Assistant Secretary read the following which was approved by the House of Delegates at the 1933 Meeting.

WHEREAS, at the time of the passage of the Medical Practice Act, and for many years thereafter, it was the accepted interpretation that the administering of an anesthetic by any one except a licensed physician or dentist was illegal, and this also was evidenced by the ban on the administering of anesthetics by duly licensed osteopaths, and

WHEREAS, during the past ten years or so there has been an insidious usurping of the duties and rights of duly licensed physicians by lay technicians and nurses who administer anesthesia despite the fact that there has been no change in the Medical Practice Act; and

WHEREAS, during this same period there have been marked advances in the physiological, chemical, mechanical, and therapeutic problems involved in anesthesia to none of which non-medical technicians have made any contribution; and

WHEREAS, these advances have reached a stage where they require a medical education for their proper interpretation and safe utilization; and

WHEREAS, the present custom in many hospitals of having nonmedical technicians administer anesthetics deprives the residents or internes of opportunities for instruction in this important branch of medicine, yet these same doctors, untrained in anesthesia, will subsequently be the ones the law assumes to be qualified to give, supervise, and to accept full responsibility for the administration of the anesthesia; and

WHEREAS, the inroads of these technicians have tended to discourage medical graduates from entering this field of medicine, and have decreased the likelihood of qualified medical successors to those who have been so instrumental in advancing the art and science of anesthesia; and

WHEREAS, the giving of an anesthetic involves on the part of the operator the exercise of judgment, discretion and skill, and is not merely a mechanical performance which can be routinely performed by any untrained individual without jeopardy to the patient; and

WHEREAS, the successful administration of anesthesia requires the exercise of proper medical care during the procedure, involves an examination of a patient to determine his physical ability to undergo the process and a careful watching of the patient during the administration of the anesthesia to determine its effects and the quantity administered; and

WHEREAS, the prevalent custom of evasion of the spirit of the law by the technical assumption of responsibility by the operating surgeon is a mere subterfuge, as the surgeon in most hospitals rarely selects or inquires into the technician's qualifications, does not usually supervise the administration of the anesthetic at its most critical period, namely the induction, and even though present during its maintenance the surgeon, because of his interest in the operative procedure, cannot always promptly detect the necessity for therapeutic intervention, which determination must be left to the judgment of the anesthetist; and

WHEREAS, many hospitals and private sanitarium advertise to the public and the profession that an anesthetist will be available; this being a misrepresentation when such anesthetist is only a technician, while the general assumption is that the term anesthetist implies a physician; and

WHEREAS, since the surgeon is by law responsible for the act of an agent, if in fact the lay anesthetist is the doctor's agent when administering an anesthetic, the surgeon assumes a responsibility and liability which under certain circumstances may nullify the effect of his malpractice coverage if it can be proved that such lay anesthetist is performing an unlawful or illegal act; and

WHEREAS, our acquiescence to the encroachment by nonmedical technicians in the field of anesthesia, on the prerogatives of the physician, will make it increasingly difficult to exclude the osteopaths and others from these same privileges, for if any division of medicine desires to nullify any section of the Medical Practice Act it can do so by the subterfuge of assuming the responsibility, then other divisions of medicine must, in justice, be accorded the same privilege and the whole Act be thus weakened. Therefore be it

RESOLVED, that the Medical Society of the State of New York affirm that the giving of an anesthetic constitutes the practice of medicine and insists on the strict observance of the provisions of the Medical Practice Act, without subterfuge or evasion; and be it further

RESOLVED, that if it is the opinion of the Attorney-General that nonmedical technicians practicing anesthesia are not violating the law under present conditions, that the proper procedure be instituted to obtain legislation which will include anesthesia in the practice of medicine or limit the administration of anesthesia to duly licensed dentists or physicians.

DR. GOODRICH, of Kings: One of the tasks of the Committee on Economics in the past year has been to consider encroachments on the practice of medicine made by hospital organizations. A subcommittee from members of the State Society was named to meet a subcommittee from the State Hospital Association to discuss anesthesia. We have, after five meetings, formulated a report which will ultimately come to this Society. I can say, for your information, that this report agrees that in from three to five years the anesthetic department of the hospitals will be reorganized and headed by a full-time professional anesthetist, certified.

I can also tell you that there are a number of other reasons why it might be not wise to forward this resolution to the American Medical Association, although like all of you here I am thoroughly favorable to the spirit of the resolution.

For instance, there are two states which legalize the nurse anesthetist. There are several states where the attorney-general has ruled that the giving of anesthesia is not practicing medicine. The present Attorney-General of this State has declined to rule until this Society brings a trial case.

There is in the middle west now a movement to have all departments of anesthesia organized, under certified specialists and they are away ahead of us in this movement on this question.

All these things seem to bear on the question of whether we should or should not pass this resolution to bring so controversial a matter on the floor of the American Medical Association.

We may be on our way to a solution; in fact it seems perfectly possible that this state society and the State Hospital Association might lead the way out of this very rank error and show the light to many other states.

A vote was taken and the motion carried.

41. SOCIETY OFFICES

Section 14

DR. HAMILTON, of New York: "WHEREAS, the offices of the Society in New York City are in a very inaccessible location, and

WHEREAS, the journey to said offices either for out-of-town members or those living within the

city of New York is thus made unnecessarily tedious, be it

RESOLVED, that the Board of Trustees or Council be requested to secure a more central location for the State offices at the expiration of the present lease."

The Committee on New Business C makes a recommendation that the resolution submitted by County of the Bronx in reference to the location of the executive offices of the Medical Society of the State of New York be disapproved

I move the adoption of the recommendation.

Motion seconded and carried

42 WORKMEN'S COMPENSATION ARBITRATION BUREAU

Section 9

On the resolution submitted by Dr Heyd
'WHEREAS, each constituent County Medical Society of the Medical Society of the State of New York sets up a different procedure for the adjudication of cases that come under the Workmen's Compensation Act, and

WHEREAS, it is apparent that each County cannot afford the necessary expense incident to the creation of an arbitration tribunal, and

WHEREAS, it is highly important that the Medical Society of the State of New York should sponsor and further the idea of arbitration in cases of dispute under the Workmen's Compensation Act, be it

RESOLVED, that the House of Delegates instruct the Executive Committee to set up a Bureau of Compensation Arbitration for the State of New York with regional branches, and further to allocate the costs of the service

To create thereby the precedent of the Medical Society of the State of New York handling Workmen's Compensation Insurance problems"

The Committee on New Business C recommends the disapproval of resolution submitted by Dr Heyd, in reference to the establishment of state wide Workmen's Compensation Arbitration Bureau for the following reasons

(1) *Local Problem* That such cases in dispute are better understood, controlled and arbitrated by a group or economic committee, in a component county society

(2) *Expenses.* That the establishment of such a bureau would add an increased and unnecessary financial burden on the State Society

I move the adoption of the recommendation

Motion seconded

THE SPEAKER The Reference Committee's recommendation is before you Any discussion?

DR ROSENTHAL, of New York I am sorry to have to disagree with the recommendation of the Reference Committee I think the Workmen's Compensation Arbitration Bureau is necessary for the whole state Various county societies have problems of difficulties arising between doctors and insurance companies on compensation matters No Bureau has been set up for the handling of these matters except in a few counties We in New York County have been able to some degree to obtain a voice in compensation work through the establishment of this Bureau If you gentlemen disapprove the establishment of such a Bureau and make no provision for the handling of disputes which arise between insurance companies and doctors in compensation work considering the fact that the Report of the Governor's Committee on Workmen's Compensation was thrown out by the

Legislature, how are you going to handle these issues?

Last year eight million dollars was expended for medical costs in New York and in those counties where physicians had authorization that money was segregated to a few If we can eliminate the need for authorization and spread that amount of money to all the physicians in the state, then you can all see that it would add definitely to the income of every physician

DR ROONEY, of Albany I don't believe I heard the report that we should disapprove the question of arbitration as a principle I think we are all for that I am rather fearful that if this recommendation of the Reference Committee is adopted as it stands, it might be construed to mean that they reject arbitration as a principle

I would move a substitute for the resolution of the Committee that this Society approve the plan of arbitration in relation to medical services under the Workmen's Compensation Law, and that it disapprove the plan proposed by the resolution Further, that it refer the report of the Reference Committee to the Council for such consideration during the coming year as may enable it to put into effect the principle of arbitration as may be established by the bill which will be introduced in the legislative session of 1935

THE SPEAKER Do I hear support for the substitute?

DR GOODRICH, of Kings I second Dr Rooney's motion

A vote was taken and the motion by Dr Rooney carried

43 ALCOHOL CONTROL

Section 18

DR. HAMILTON, of New York On the resolution presented by the Medical Society of the County of Monroe

"WHEREAS, the Constitution of the Medical Society of the State of New York clearly sets forth the purpose of the Society, 'to secure the enforcement of just medical laws, to enlighten and direct public opinion in regard to the great problems of medicine,'

WHEREAS, the Alcoholic Beverage Control Law, delegating to respective County Medical Societies the responsibility of nominations of local commissions, assigns to the Society an action that is not concerned with a great medical problem and is outside of the proper field of activity of the Society,

WHEREAS, with the probable repeal of the Eighteenth Amendment, the County Societies will have their duties extended in this field,

WHEREAS, the further discharge of such duties will tend to jeopardize the honorable professional standing which the Medical Society of the County of Monroe has sustained in its other activities, it is therefore

MOVED, that the Medical Society of the County of Monroe take a definite stand in regard to its activities in this politico-social problem it is further

MOVED, that this Society go on record as being opposed to further functioning in this field of activity, and be it further

MOVED, that this action be transmitted to the Medical Society of the State of New York both by our delegates at the next annual meeting and in any other way that the Comitia Minora sees fit

The Committee on New Business C recommends that the resolution proposed by the Medical Society of the County of Monroe "That the Society go on record as being opposed to any further functioning in the field of alcoholic beverage" be approved.

I move its adoption.

Motion seconded and carried.

44. SOCIALIZATION OF MEDICINE

Section 27

DR. HAMILTON, of New York: Reporting on the following resolution:

"WHEREAS, in the report of our President of the State Society, there is immediate danger for the socialization of medicine by lay bodies, and

WHEREAS, in the *Journal of the American Medical Association* an editorial on May 12th states that there is a trend toward a change in the present form of medical practice, and

WHEREAS, a large group of physicians in New York City have already formulated a plan, be it

RESOLVED, that the Committee on Economics investigate the plans proposed and report at the next session of the House of Delegates."

The Committee on New Business C recommends approval of the resolution submitted that the further study of the problems of Socialized Medicine be continued by the Committee on Economics for report at the next session of the House of Delegates.

I so move. Seconded.

DR. ROONEY, of Albany: There is a report of a committee to be heard later that concerns this very question. I would move you that this resolution of the Reference Committee be tabled, to be taken up at the same time with the report of this other committee appointed by the Executive Committee, when it makes its report.

Motion seconded and carried.

45. SCHOOL VACATIONS

Section 20

DR. HAMILTON, of New York: On the resolution submitted by the Medical Society of the County of Chautauqua:

"WHEREAS, the school year in the state does not end until the latter part of June, allowing only July and August for vacation for the children, and

WHEREAS, the Chautauqua County Medical Society did go on record as favoring a shortening of the vacations throughout the school year, that school might be dismissed earlier in June, be it

RESOLVED, that the Medical Society of the State of New York recommend that the State Department of Education close the public schools of the State not later than the middle of June."

It is the opinion of the Committee on New Business C that the subject of the resolution proposed by the Medical Society of the County of Chautauqua in re school year, does not involve a question of general interest to the medical profession and is, therefore, not a proper subject for action on the part of the House of Delegates.

I so move.

Seconded and carried.

46. X-RAY LABORATORIES

Section 15

DR. HAMILTON, of New York: On the resolu-

tion introduced by the Medical Society of the County of the Bronx:

"WHEREAS, the making of a diagnosis by means of the x-ray and/or the administration of x-rays, or other radiant energy for treatment, are methods of diagnostic or therapeutic medical practice, and

WHEREAS, the Medical Practice Act makes the diagnosing and/or treatment of disease unlawful for anyone not duly licensed to practice medicine, and

WHEREAS, during the past ten years or more lay persons and lay organizations have established and are conducting x-ray laboratories in which lay persons are examining and/or treating patients by means of x-rays, and

WHEREAS, such lay persons are not properly qualified and are not subject to effective supervision or control, and

WHEREAS, the x-rays in the hands of inexperienced and/or irresponsible persons are in themselves a potential source of injury to the patient, and

WHEREAS, in addition to these dangers x-ray diagnosis frequently requires the administration of potent drugs or chemicals which may be legally administered only by licensed physicians, and

WHEREAS, under these conditions the lay x-ray operator and the commercial x-ray laboratories constitute a menace to the public and in addition are strictly commercial enterprises conducted by business getters who are actuated by the profit motive and who consequently do not feel themselves bound by the rules of medical ethics, but who resort to all sorts of questionable methods to attract a complaisant clientele, and

WHEREAS, by the employment of solicitors, runners and/or other business agents and by the promise of rebates or of favorable or dishonest diagnoses, obtain the patronage of unscrupulous physicians or of business and industrial organizations to the detriment of the patient, and

WHEREAS, because of their illegal activities and the desire for profit they have been unable to attract competent physicians adequately trained in radiology and as a result employ the services of individuals whose education, training and character are unacceptable to right thinking members of the medical profession or to the American Medical Association, and

WHEREAS, the technical diagnostic and therapeutic advances being made in radiology are due to, and dependent upon, properly trained physicians to whom science must look for further progress in the field of radiology, and

WHEREAS, the lay x-ray technicians and laboratories have so encroached upon the practice of radiology that competent and ethical medical practitioners find it more and more unattractive as a field of endeavor, thus endangering the progress and advancement of the science of radiology and the welfare of the public, be it therefore

RESOLVED, that the House of Delegates in convention assembled believes that the practice of radiology whether for diagnostic or therapeutic purposes, constitutes in fact the practice of medicine, and be it further

RESOLVED, that the properly constituted authorities be called upon to take the requisite steps to bar all persons not licensed to practice medicine in the State of New York from the practice of radiology, and be it further

RESOLVED, that if it is the opinion of the Attorney General that nonmedical technicians, practicing radiology are not violating the law under present conditions, such steps be taken to institute legislation which will include radiology in the practice of medicine and to limit diagnostic or therapeutic x ray work to duly licensed physicians or dentists, and be it further

RESOLVED, that our delegates from New York to the American Medical Association be instructed to bring this matter to the attention of the House of Delegates of the American Medical Association at the impending session"

The Committee on New Business C recommends the approval by the House of Delegates of the resolution introduced by the Medical Society of the County of the Bronx relative to the practice of radiology for diagnostic or therapeutic purposes with the following suggested amendment

That if it is the opinion of the Attorney-General that nonmedical technicians, practicing radiology are not violating the law under present conditions such steps be taken to institute legislation which will include radiology in the practice of medicine and to limit diagnostic or therapeutic x ray work to the direct and active supervision and control of duly licensed physicians or dentists"

I move its approval

Motion seconded and carried

47 REPORT OF REFERENCE COMMITTEE ON REPORT OF LEGAL COUNSEL

DR. LEITNER, of Rockland We wish to call attention to the increasing amount of work performed by the Legal Department of this Society

Report this year covers a period of thirteen months An increased number of cases were instituted over the preceding year

Mr Lorenz J Brosnan, our Counsel is ably assisted by his associates, Mr Thomas H Clearwater and Mr William F Martin, and with a very efficient office force, the work assigned to the Legal Counsel has been performed in a creditable manner Due recognition is given to the able cooperation of the officers of the Medical Society of the State of New York

Again we wish to emphasize the growing number of malpractice actions being instituted against members of the medical profession and the need of proper and adequate protection against such actions

The former Chairman of the Insurance Committee the late Dr John A Card worked earnestly to effect the Group Plan of Insurance, and his successor, Dr Frederic E Sondern, has carried on the work of the Committee in a very efficient manner

We note that there were commenced in the present thirteen months recording period, two hundred and thirty actions as against two hundred and twenty five during the previous eleven months reporting period Two hundred and four actions were disposed of as against one hundred and fifty eight during the preceding reporting period

Of the two hundred and four actions disposed of during the reporting period, forty one have been settled In one hundred and sixty actions, judgments were obtained for the defendant after

trial or they have been disposed of through dismissal, discontinuance, or abatement

In three cases only were judgments rendered in favor of the plaintiff

From the report we also note that favorable results were obtained in five cases which were in the Appellate Division

In addition to the handling of the cases it is apparent that the counsel is doing a tremendous volume of work in an advisory capacity to the Officers and members of the Society

This brief summary gives some idea of the amount of work being handled by our Legal Department and the efficient manner in which it is being accomplished

The editorials and case reports covering a wide variety of subjects during the year have been of the same high standard and very instructive to the members

The Committee feels that more attention should be given to these articles and the information contained therein should be compiled and printed in some way for permanent reference

We note that but *fifty six per cent* of our members are insured under the Group Plan

In conclusion the Committee again wishes to emphasize the great importance of the Group Plan of Insurance and the growing need for adequate protection of the medical profession against malpractice actions

Our Legal Department is in every way worthy of our commendation and confidence

I move the adoption of this report

Motion seconded and carried

48. BROADCASTING

Section 17

DR WARREN of Kings Your Reference Committee on New Business B reports on the resolution offered by Dr Wightman

'WHEREAS, the various broadcasting stations are being used by some drug and patent medicine manufacturers to exploit and make exaggerated and false claims for their products to the serious danger of public health be it

RESOLVED that the Medical Society of the State of New York go on record as favoring a Central National Clearing Bureau of the medical profession which shall act as a reference committee to confer and advise the broadcasting systems in accepting questionable material"

The Committee approves this resolution, substituting for the words in accepting questionable material' the following As to the propriety of accepting commercial programs advertising various proprietary and household remedies"

The Committee further recommends that the delegates of the Medical Society of the State of New York to the American Medical Association be instructed to submit this resolution and urge its adoption by that body

I move its adoption

Motion seconded and carried

49 UNETHICAL MEDICAL ADVERTISING OVER THE AIR

Section 23

DR. WARREN, of Kings The second matter referred to this Committee is the resolution presented by Dr Saxl of New York, is one dealing with the same matter

"WHEREAS, it has become increasingly apparent to members of the Society that advertising over the air has become increasingly more unethical, and

WHEREAS, the County Societies in the metropolitan district, have through their various committees, succeeded in obtaining only a moderate degree of cooperation with the radio broadcasting stations with a view of causing a cessation of unethical medical advertising over the air, and

WHEREAS, the broadcasting stations are calling upon organized medicine for support in the arrangement of sustaining programs, and

WHEREAS, organized medicine and members of the medical profession have cooperated with the broadcasting stations to provide informative medical programs of interest to the public and in the interest of the public health, over the air, and

WHEREAS, the American Medical Association has made arrangement with national broadcasting organizations to provide such sustaining programs for them from the headquarters of the American Medical Association in Chicago, therefore, be it

RESOLVED, that the delegates of the Medical Society of the State of New York to the House of Delegates of the American Medical Association bring to the attention of the House at the impending session in Cleveland, the fact that organized medicine and the medical profession are dissatisfied with the quality of commercial programs advertising various proprietary and household remedies, and believe that these programs are of such a nature as to be inimical to the welfare of the people and detrimental to the interests of the medical profession, therefore, be it further

RESOLVED, that our delegates call upon the American Medical Association to take such steps as they may deem advisable and necessary to cause an improvement in radio broadcasting and a cessation of unethical practice as above outlined, over the air."

Your Committee feels that as this matter deals with the one previously mentioned, namely, the evils of present-day broadcasting of proprietary and patent medicines, your Committee believes that the purpose of the resolution is covered in the resolution just presented, and has no recommendation to make.

THE SPEAKER: The report of the Committee is that no action shall be taken on the resolution. Moved and seconded.

THE SPEAKER: The question before the House is that no action shall be taken on the resolution.

THE SPEAKER: The chair is in doubt. All those in favor of the motion adopting the report of the Reference Committee that no action shall be taken on this resolution will kindly rise. * * * * Those opposed kindly rise. * * * * The motion is carried.

50. REMITTING OF DUES

Section 13

DR. WARREN, of Kings: The third matter referred to this Committee was a resolution by Dr. Podvin of the Bronx as follows:

"WHEREAS, it is the practice of County Societies to continue on their roll of membership certain members who are financially unable to pay the regular dues, and

WHEREAS, it is required that the local society remit the amount of ten dollars for each such member to the State Society, and

WHEREAS, this causes a severe strain on the finances of the County Society, be it

RESOLVED, that on the certification of the President and Treasurer of a County Society the State dues for such member be remitted and be it further

RESOLVED, that the member or members thus excused from paying dues shall not exceed five per cent of the number of members in good standing of said County Society, and be it further

RESOLVED, that each member whose dues are thus, remitted shall sign an agreement to pay back to the State Society the amount due as soon as he is in funds."

Your Committee is sympathetic with the spirit of the resolution but cannot approve it, and believes that the responsibility in this matter should remain at least temporarily with the County Society where it exists at present, and so recommends.

I move the adoption of the report.

Seconded and carried.

51. "CONTRACT" MEDICAL CARE

Section 22

DR. WARREN, of Kings: The fourth matter referred is a resolution as follows:

"WHEREAS, the principles of professional conduct established by the Society are/or may be implicated and compromised in plans to provide cheap or 'contract' medical care, therefore, be it

RESOLVED, that we reaffirm our position in these words:

It shall be considered unethical and unbecoming a gentleman and a physician to participate or engage in any plan, scheme or program, of institutional activity for the provisions of medical care through any agency which commercialize such care by solicitation in the form of printed, written or spoken advertisement distributed or displayed to or through lay or nonmedical channels.

And further, the self-appraisal by laudatory claims of unusual or superior character of facility of service, or the setting up by an institution or plan of a schedule of 'cut-rate' fees for medical or surgical care, shall be considered to be the acts of each individual employed or engaged therein, and for which conduct he shall be held accountable to and subject to discipline by the County Medical Society."

The Committee believes that there is no recommendation necessary for this resolution as the subject presented is thoroughly covered in paragraph 31-B of the Principles of Professional Conduct of the Medical Society of the State of New York.

We therefore ask for no action.

52. POOLING RESOURCES OF PERSONS WITH LIMITED EARNING CAPACITY

Section 19

DR. WARREN: The next matter which was considered was the resolution by Dr. Ferber:

"WHEREAS, a Committee appointed by the House of Delegates of the State Medical Society of Michigan, in September, 1931, in its report rendered July, 1933, shows that 92 per cent of

the people receive but 65 per cent of the total annual income of the population, and

WHEREAS, this same Committee in a study of the living costs of this 92 per cent of the population found that it ranged from \$42.00 below to \$443.00 above the family income, and

WHEREAS, this Committee also reports that whenever income was found in excess of living costs, it was also shown that medical care must compete with insurance, transportation, education and inner urges that draw on the reserve that remains over the living expenses, and medical care is always the weakest, least considered competitor, and

WHEREAS, the statistics of the United Hospital Fund in New York show a constant and alarming increase in the attendance in the free dispensaries—the total number of individuals treated in the dispensaries in 1920 being 927,421, whereas in 1932 about 2,500,000 individuals were given free treatment by the doctors in the dispensaries with a total number of 7,623,765 treatments, and

WHEREAS, this alarming increase in the free treatments by physicians was constant and progressive even before and therefore not mainly caused by the depression, and

WHEREAS, this increasing burden of medical charity added to the constantly declining income of the doctor very seriously threatens his economic position, therefore, be it

RESOLVED, that a Committee be appointed by the properly constituted authority of our State Society for the purpose of devising some plan whereby people with limited earning capacity can pool their resources in order to have funds available to pay for their medical care. This Committee is to report to the House of Delegates at the next Annual Meeting.

The Committee feels that there should be no duplication of effort in our organization and as the Economic Committee of our Society is gathering facts and making detailed study of matters presented in this resolution, we recommend that the resolution be referred to the Committee on Economics

I so move

Seconded and carried

53 FEDERAL COMPENSATION BUREAU—CHOICE OF PHYSICIANS Section 8

DR. WARREN WHEREAS the procedures established by the Federal Works Administration are inimical to the best interests of the doctor as the Federal Compensation Bureau have refused any form of free choice of physicians,

WHEREAS, the doctors are citizens as other members of the community, they should not be discriminated against in the matter of their professional work, be it therefore

RESOLVED, that the House of Delegates instruct its delegates to the American Medical Association to present the views of this House to the American Medical Association so that there may be established a united policy which will justly and adequately protect the physician.

Your Committee recommends its adoption with

choice of physicians, and established by the
do not allow free

WHEREAS, the doctors as citizens should not be discriminated against in their professional work, be it

RESOLVED, that the House of Delegates instruct its delegates to the American Medical Association to present this matter and urge the association to attempt a change of rules of the Federal Compensation Bureau which will allow the injured person free choice of physician.

I so move

Seconded and carried

54 REPORT OF REFERENCE COMMITTEE ON THE REPORT OF THE COMMITTEE ON SCIENTIFIC WORK AND ARRANGEMENTS

DR. HEYL, of Westchester Your Reference Committee on the Report of the Committee on Scientific Work and on the Report of the Committee on Arrangements is conscious of the magnitude of the work of these committees

The Scientific Program in its general sessions presents two subjects of vast importance to the practice of medicine. The symposium on Growth and Reproduction should stimulate an interest in the reasonable application of such knowledge which is new and all too often given an unjust hearing or trial because of failure in the past, due to incomplete knowledge and impotent products

The same might be said for the symposium on Forensic Medicine. There may be nothing new under the sun but there are always new and often better avenues of approach to any goal.

There are eleven separate Special Section programs representing a total of some seventy seven different subjects all indicating authoritative presentation of material pertinent to present and future day needs.

Mention must be made of the Scientific Exhibit which alone could supply more information than any one would attempt to assimilate in three days. More than twenty five separate subjects and demonstrations are presented many purposely related to the various Section titles.

The Committee on Arrangements has clearly stated the location order, and plan for the various separate and interlocking meetings sessions, dinners, and entertainments. Utilizing two hotels and a church house, which are in fair proximity, and centralizing in each certain section meetings, with the Scientific Exhibit all in one, they have done well where all could not be housed under one roof. The Committee for the entertainment of the ladies has provided for them an enjoyable interlude.

The promise of The Donovan Affair by the renowned Players' Club including "professional talent, is a noteworthy departure from precedent.

They are to be congratulated for having had the President of the American Medical Association Dr. Dean Lewis accept their invitation to be the guest of the Medical Society of the State of New York and address it at the Annual Banquet, on Tuesday evening. Your Committee sincerely urges all present at the Annual Meeting to include this portion of the program in the proper fulfillment of their schedule.

This Reference Committee can only applaud the efforts of the chairmen and their associates in what they have accomplished.

I move that this report be adopted

Motion seconded and carried

55. REFERENCE COMMITTEE ON PRESIDENT'S
REPORT

Section 4

DR. BUETTNER, of Onondaga: We appreciate the President's interest in the practice of medicine in general. The Committee agrees with his views on the practice of medicine by hospitals, medical centers and lay organizations and urge that these practices be discouraged.

We concur in his views that the family physician should examine school children, give toxin-antitoxin, etc.

We recommend the treatment of syphilis by the physician rather than by any clinic.

We commend the President in his efforts to assist the Committee on Public Relations by attending some of its conferences.

We are in favor of the President's opinion on the meeting of County Societies at least once a month and on his views that all County Societies have representatives to work on various committees such as Public Relations, Economics, Legislation, etc.

We approve the idea of a full-time field officer for purposes as outlined by the President.

This committee agrees with the President's views on dues.

We recommend its adoption.

Motion seconded and carried.

56. REFERENCE COMMITTEE ON PRESIDENT-ELECT'S
REPORT

Section 5

DR. BUETTNER, of Onondaga: The committee does not agree on all points in the incoming President's report. They appreciate that the practice of medicine must change with the trend of the time and the committee does not feel that they can do justice to this report in the time allotted, but, recommends that the appropriate standing committee or a new committee be appointed to take this matter under consideration and to study it and bring in further recommendations at our next meeting.

We approve the recommendation to inject new blood into our standing committees, insofar as not to impair their present efficiency.

We endorse the recommendation of the President-elect that no member of a Committee be permitted to address any organization on matter under consideration by his committee without sanction of the executive committee.

We endorse the recommendations relative to the new JOURNAL and trust sufficient space will be given to all the activities of the State Societies and its component parts.

We submit the report and ask for its approval.

Motion seconded.

DR. BUETTNER: We recommend that the whole report be re-studied.

Motion seconded.

DR. ROONEY, of Albany: I am rather in doubt as to just exactly what the committee means. I would like to have it clarified. I am going to move a substitute.

I move that we substitute for the Reference Committee's report on the address of the President-elect, to wit: that new blood be infused into the standing committees by the addition to each standing committee of a young new member each year for the purpose of increasing his training and education in the work of the Society. That is the first one. The second one is on an

important matter that has caused the State Society a great deal of trouble in past years, individual members of committees making premature announcements on incomplete and inconclusive work of the committee.

I so move.

DR. BUETTNER: In this report we approve the recommendation to inject new blood into our standing committees so far as not to impair their present efficiency; and endorse the recommendation of the President-elect that no member of a committee be permitted to address any organization on matter under consideration by his committee without sanction of the executive committee.

DR. ROONEY: The substitute motion is that we substitute for the entire report of the reference committee on the address of the President-elect, the President-elect's two recommendations with no other matter.

Motion seconded and carried.

57. OSTEOPATHY

Section 6

DR. MASTERSON, of Kings: Your Reference Committee on Report of the Committee on Legislation reports on the following resolution:

"WHEREAS, osteopathy is a system of treating disease wherein drugs are not used, and

WHEREAS, in the training of osteopaths in the State of New York, the use, nature and action of drugs is not taught, and

WHEREAS, there is a bill (Assembly Int. 2,118, print 2,443) which has passed both Houses of the State Legislature and is now before the Governor, and which would permit osteopaths to use any and all drugs in the practice of their profession, and

WHEREAS, the bill is indefinite in its construction and we believe impossible of administration, therefore, be it

RESOLVED, that the House of Delegates of the Medical Society of the State of New York hereby express its concern for the public welfare, should this bill become a law, and be it further

RESOLVED, that this House of Delegates communicate its concern to His Excellency, the Governor, and inform him of the dangers of permitting unqualified men, who have not the educational requirements established by the regents of the State of New York for those who prescribe drugs and, therefore, respectfully requests the Governor to veto this bill in the interest of the public."

We move the adoption of this resolution and that a delegation to the Governor be sent immediately, and also that the secretary of this Society write a letter to the Governor this evening, enclosing a copy of this resolution.

I so move.

Motion seconded and carried.

58. REPORT OF REFERENCE COMMITTEE ON THE
REPORT OF THE COMMITTEE ON LEGISLATION

DR. MASTERSON, of Kings: Your Reference Committee approves of the report of the Committee on Legislation. The work required of this Committee is becoming more arduous each year. During the last session of the Legislature one hundred and eighty bills having some relation to public health, the practice of medicine, or the activities of physicians were introduced. The Committee had to carefully study each bill, send copies of the more important ones to the Chair-

men of the County Committees with a request for comment. This will give the House of Delegates some slight idea of the enormous work required of this Committee. Many times in the course of the legislative session immediate action is required on some bills and the committee must use their best judgment as to the proper course to pursue. We have every reason to believe that in the future the work required of this committee will be increased instead of lessened.

The question naturally arises as how best to handle this work and how it may become a more effective force in opposing legislation inimical to the public health and the medical profession and having bills passed which we sponsor. The legislative committee, we believe, have done all that could be humanly expected of them, considering that their work is purely voluntary and they have to pursue the practice of their profession for their livelihood.

The report states that our executive officer, Dr. Lawrence, has been very courteously received by the various members of the committees in the Legislature and has been of great assistance to the Committee at Albany. Nevertheless, during the past session the Osteopath Bill passed both houses of the Legislature, the Hospital Lien Bill and Nurse Anesthetist Bill were defeated, and the bill amending the Workmen's Compensation Law that was proposed to cure all the evils in the present law was so emasculated by amendments that we had to let it die in committee. The passing of the Osteopath Bill and the failure of passage of the other bill must not be construed as a criticism of the Legislative Committee or our Executive Officer, but is due rather to our lack of properly organized power at Albany. This statement is made with the full knowledge that the passage of a bill is not always a simple matter.

We would recommend that the bulletins of progress of the Legislative Committee be sent to each member of every County Legislative Committee. This committee would also recommend that the executive committee give serious consideration to the question of employing a qualified executive to assist the work of our executive officer in Albany. We feel that a larger personnel is required at Albany during the legislative session.

I move its adoption as a whole.

THE SPEAKER This recommendation carries with it the employment of additional help at Albany.

THE SECRETARY That has to be referred to the council.

Motion seconded.

A vote was taken and the motion carried.

59 REPORT OF THE REFERENCE COMMITTEE ON THE SUPPLEMENTARY REPORT OF THE COMMITTEE ON LEGISLATION

Section 26

DR. MASTERSON, of Kings The Reference Committee emphasizes the necessity of impressing upon the individual members of the County Societies the need of regarding more seriously legislation which is inimical to public health and to the medical profession. We urge that the legislative committees of the County Societies take more aggressive action in promoting expressions of opinion from their membership during the meetings.

The interest of lay groups in matters pertaining to public health is strongly recommended but we feel that it must be initiated and controlled by the County Societies rather than by action of the House of Delegates.

We recommend that the Hospital Lien Bill and the Clinical Laboratory Bill be reconsidered and if possible resubmitted to the Legislature at the next session.

We approve the suggestion that more vigorous action to arouse interest in the Hospital Dispensary Bill and the Nurse Anesthetist Bill be taken in order that they may be more favorably received in the future.

I move the adoption of the report as a whole.
Motion seconded and carried.

60 LEGISLATIVE COMMITTEE TO MEET EVERY TWO WEEKS

Section 11

DR. MASTERSON, of Kings In regard to the resolution introduced, requiring the Legislative Committee to meet every two weeks or more often during the session of the State Legislature this Committee recommends the disapproval of this resolution for the following reasons.

We feel that it is unjust to require this Committee to meet at stated intervals, for this would entail undue inconvenience on the part of the members and might not be warranted by existing circumstances. These compulsory meetings would increase the expenses of the Committee greatly. The Chairman and members of the Committee should be entrusted with the decision as to the necessity for calling sufficient meetings to properly protect the interests of this Society.

I move its adoption.
Motion seconded.

THE SECRETARY I introduced that resolution solely with the idea of expediting matters legislative.

DR. ROONEY, of Albany We are dealing with the same old situation. I feel that there is one thing that has got to be done, and that is get a representative of the Legislative Committee in Albany. I think there is another thing that has to be done the Legislative Committee has to meet in Albany and not in New York.

The third thing to be done is to get rid of the impression being created in the Legislature of the State of New York in the last four years, that we have a lobbyist.

I think that this whole question should be referred to the Executive Committee for a study with a view of revamping our whole legislative situation as it is concerned in this Society, and I so moved it as a substitute motion.

Motion seconded.

DR. ROONEY Any criticism that may be directed at the Legislative Committee is directed at the machine and not the man. The machine is antiquated. We can afford, and we should afford, something better.

A vote was taken on the motion to refer this whole matter to the Executive Committee, and the motion was carried.

61 REPORT OF REFERENCE COMMITTEE ON REPORT OF SECRETARY

DR. KRIEGER, of Dutchess Putnam Your Reference Committee feels that the Society cannot sufficiently express its sense of obligation and

55. REFERENCE COMMITTEE ON PRESIDENT'S REPORT Section 4

DR. BUETTNER, of Onondaga: We appreciate the President's interest in the practice of medicine in general. The Committee agrees with his views on the practice of medicine by hospitals, medical centers and lay organizations and urge that these practices be discouraged.

We concur in his views that the family physician should examine school children, give toxin-antitoxin, etc.

We recommend the treatment of syphilis by the physician rather than by any clinic.

We commend the President in his efforts to assist the Committee on Public Relations by attending some of its conferences.

We are in favor of the President's opinion on the meeting of County Societies at least once a month and on his views that all County Societies have representatives to work on various committees such as Public Relations, Economics, Legislation, etc.

We approve the idea of a full-time field officer for purposes as outlined by the President.

This committee agrees with the President's views on dues.

We recommend its adoption.

Motion seconded and carried.

56. REFERENCE COMMITTEE ON PRESIDENT-ELECT'S REPORT Section 5

DR. BUETTNER, of Onondaga: The committee does not agree on all points in the incoming President's report. They appreciate that the practice of medicine must change with the trend of the time and the committee does not feel that they can do justice to this report in the time allotted, but, recommends that the appropriate standing committee or a new committee be appointed to take this matter under consideration and to study it and bring in further recommendations at our next meeting.

We approve the recommendation to inject new blood into our standing committees, insofar as not to impair their present efficiency.

We endorse the recommendation of the President-elect that no member of a Committee be permitted to address any organization on matter under consideration by his committee without sanction of the executive committee.

We endorse the recommendations relative to the new JOURNAL and trust sufficient space will be given to all the activities of the State Societies and its component parts.

We submit the report and ask for its approval.

Motion seconded.

DR. BUETTNER: We recommend that the whole report be re-studied.

Motion seconded.

DR. ROONEY, of Albany: I am rather in doubt as to just exactly what the committee means. I would like to have it clarified. I am going to move a substitute.

I move that we substitute for the Reference Committee's report on the address of the President-elect, to wit: that new blood be infused into the standing committees by the addition to each standing committee of a young new member each year for the purpose of increasing his training and education in the work of the Society. That is the first one. The second one is on an

important matter that has caused the State Society a great deal of trouble in past years, individual members of committees making premature announcements on incompleting and inconclusive work of the committee.

I so move.

DR. BUETTNER: In this report we approve the recommendation to inject new blood into our standing committees so far as not to impair their present efficiency; and endorse the recommendation of the President-elect that no member of a committee be permitted to address any organization on matter under consideration by his committee without sanction of the executive committee.

DR. ROONEY: The substitute motion is that we substitute for the entire report of the reference committee on the address of the President-elect, the President-elect's two recommendations with no other matter.

Motion seconded and carried.

57. OSTEOPATHY Section 6

DR. MASTERSON, of Kings: Your Reference Committee on Report of the Committee on Legislation reports on the following resolution:

"WHEREAS, osteopathy is a system of treating disease wherein drugs are not used, and

WHEREAS, in the training of osteopaths in the State of New York, the use, nature and action of drugs is not taught, and

WHEREAS, there is a bill (Assembly Int. 2,118, print 2,443) which has passed both Houses of the State Legislature and is now before the Governor, and which would permit osteopaths to use any and all drugs in the practice of their profession, and

WHEREAS, the bill is indefinite in its construction and we believe impossible of administration, therefore, be it

RESOLVED, that the House of Delegates of the Medical Society of the State of New York hereby express its concern for the public welfare, should this bill become a law, and be it further

RESOLVED, that this House of Delegates communicate its concern to His Excellency, the Governor, and inform him of the dangers of permitting unqualified men, who have not the educational requirements established by the regents of the State of New York for those who prescribe drugs and, therefore, respectfully requests the Governor to veto this bill in the interest of the public."

We move the adoption of this resolution and that a delegation to the Governor be sent immediately, and also that the secretary of this Society write a letter to the Governor this evening, enclosing a copy of this resolution.

I so move.

Motion seconded and carried.

58. REPORT OF REFERENCE COMMITTEE ON THE REPORT OF THE COMMITTEE ON LEGISLATION

DR. MASTERSON, of Kings: Your Reference Committee approves of the report of the Committee on Legislation. The work required of this Committee is becoming more arduous each year. During the last session of the Legislature one hundred and eighty bills having some relation to public health, the practice of medicine, or the activities of physicians were introduced. The Committee had to carefully study each bill, send copies of the more important ones to the Chair-

Societies in the collection and organization of such material. This would require the services of full-time medical man, though his employment may not be feasible at this time.

I move the adoption of the report.

Motion seconded and carried.

65. REPORT OF REFERENCE COMMITTEE ON REPORT OF COMMITTEE ON PUBLIC HEALTH AND MEDICAL EDUCATION

Section 39

DR. CRITCHLOW, of Erie: This report was referred back to this committee for correction. Under "general public health activities" the report now reads:

"In these days, when the fear of 'State Medicine' is ever present in the minds of physicians, any discussion is pertinent and timely, which considers possibilities for enlarging the field of the practitioner's activities. That the work of Health Departments is seriously encroaching on the territory of the private physician few will deny. Can this expansion of departmental activities be checked by allocating to the practitioner some of the duties now assumed by the State? This, in brief, is the question propounded in the Report under review. The committee states its belief 'that this Society can introduce a plan whereby the physician will participate more directly in the field of preventive medicine,' and briefly outlines the essential features that should be embraced in such a plan.

We heartily endorse the recommendation of the committee that the House of Delegates take some action. We are of the opinion, however, if such action goes only so far as to urge County Medical Societies to consider a plan, that valuable time would be lost. We believe more direct action is better; we, therefore, recommend that the Committee on Public Health and Medical Education be instructed to formulate such a plan and refer the same to the Executive Committee for approval."

THE SPEAKER: You have heard the recommendation of the Reference Committee on the matter referred to it. What is your pleasure?

Moved, seconded, and carried that the report be accepted.

66. MATERNAL MORTALITY

DR. CRITCHLOW, of Erie: The recommendation of this committee on its report which was referred back, is now as follows:

"We would emphasize that section of the report dealing with maternal mortality. We approve the recommendation of the Committee that the House of Delegates authorize the Committee on Public Health and Medical Education to submit to the Executive Committee a plan organizing Maternal Welfare Commissions in each County Society and to advise in regard to their specific duties. We so recommend.

At the same time we believe the Committee on Public Health and Medical Education should prepare to correlate the findings of various medical organizations that have already made or in the future may make surveys of the maternal mortality problem. We so recommend.

We approve the recommendation of the Committee on Public Health and Medical Education in their supplementary report that the said Committee be instructed to study the suggested remedial measures on nursing education in New

York State, and report to the Council without delay.

Finally, we wish to express our appreciation of the services of Dr. Farmer and his Committee in bringing briefly but forcibly to our attention the subjects treated in the report under review."

I move that it be adopted.

Motion seconded and carried.

DR. CRITCHLOW: I move the adoption of the report of the Reference Committee as a whole as amended.

Motion seconded and carried.

67. RETIRED MEMBERS

Section 69

THE SECRETARY: I have on my desk the names of a number of physicians who have been recommended to the Society by their respective County Societies for election to retired membership. I move that the names be placed in the retired list.

Eugene Baker, Ithaca; Charles S. Benedict, New Rochelle; Samuel J. Bradbury, Lynbrook; George E. Brewer, New York; Sophie U. Chapman, New York; Salo Cohn, New York; Aurelius de Yoanna, Brooklyn; Duane E. Ensign, McGraw; Louis Fischer, New York; Alpheus Freeman, New York; Mary Gage-Day, Kingston; W. Travis Gibb, New York; DeWitt C. Greene, Buffalo; George L. Kilborn, Forestport; William M. Kantor, Bronx; Charles G. Koehler, Brooklyn; William T. McManis, New York; John J. MacPhee, New York; Adelbert H. Mambert, Kingston; Howard G. Myers, New York; Lewis K. Nelf, New York; Cornelius Parodi, Brooklyn; Alfred G. Pfeiffer, New York; George M. Price, New York; William J. Prish, Fredonia; Adolph Reich, New York; Clarence C. Rice, New York; Thomas E. Satterthwaite, New York; Gustavus Schlegel, New York; Gustav Seeligmann, New York; Samuel H. Slote, Brooklyn; George E. Smith, Fredonia.

DR. FLYNN, of Monroe: These men are still practicing medicine?

THE SPEAKER: Yes.

DR. FLYNN: Are they entitled to protection by the State Society for malpractice defense?

THE SPEAKER: I would prefer to give a ruling after having consulted the Counsel. He will be here in the evening session.

DR. FLYNN: I move that the matter be held over until the Counsel has been consulted.

Motion seconded and carried.

68. RESUSCITATION

Section 73

DR. ROONEY, of Albany: WHEREAS, the recent widespread and sensational publication of incomplete and inconclusive experimentation in the resuscitation of apparently dead animals has elicited false hope in the minds of the public and has led to intensive propaganda on the part of those societies actively combating proper animal experimentation, and

WHEREAS, this premature and inconclusive work adds nothing to the knowledge already had for years concerning the question of resuscitation, therefore, be it

RESOLVED, that the House of Delegates of the Medical Society of the State of New York, condemn the issuance and the publication in the lay press of this misleading and harmful account of inconclusive work prior to its consideration by the only scientific group capable of evaluating it—the profession of medicine.

THE SPEAKER: Referred to Reference Committee on New Business C.

On motion duly made, seconded and carried, the meeting adjourned to reconvene at 8:00 P. M.

EVENING SESSION, 8 P. M.

The Meeting was called to order by the Speaker.

69. RETIRED MEMBERS

Section 67

THE SPEAKER: On the subject of retired membership, the counsel has arrived and I have had a decision. In reference to the retired membership, I want to read to you the paragraphs of your Constitution and By-laws that apply to the retired membership:

"A member in good standing in his component county medical society reaching seventy years of age may ipso facto have the privilege of applying for retired membership in the State Society. All such applications shall be signed by the President and the Secretary of the County Society of the applicant and then sent to the Secretary of this Society for presentation to the House of Delegates for approval. Retired members desiring to become active members shall apply for such membership to the component county society in the county of the residence of the applicant. Such applications shall be governed by the Constitution and By-Laws of the component county society relative to active membership.

Honorary and retired members shall be entitled to the privilege of attending and addressing the meetings of the Society, but shall not be accorded the other rights and privileges of membership or be subject to assessment."

Under the opinion of counsel of the Society they are not entitled under this By-law to protection in malpractice defense unless it is amended.

In contradistinction to this, this House to-day passed a resolution on a recommendation of the Reference Committee, the recommendation of the Secretary of the Society: "Your secretary feels that an injustice is being done to this class of members, many of whom are still practicing and therefore liable to malpractice suits. He recommends that the right to malpractice defense and the privilege of insurance be granted to them." And the Reference Committee having that before it reported: "We also concur in the secretary's recommendation that the rights to malpractice defense and the privilege of insurance be granted to retired members."

Under the circumstances the Chair rules that unless an amendment to the By-laws to make these recommendations effective be presented tonight, this recommendation is out of order and contrary to the Constitution and By-laws.

THE SECRETARY: I am going to present such an amendment tomorrow morning.

DR. PHILLIPS, of New York: I move that the resolution be taken from the table and become matter for consideration later.

Motion seconded and carried.

THE SPEAKER: We are now considering as the business before the House the applications for retirement.

DR. ROONEY, of Albany: Retirement is not compulsory; it is voluntary and I would move you, to settle this question, that upon the pas-

sage by the House of the motion for the retirement of these members, the Secretary of the State Society be directed to write them at the time he informs them of their retired membership, that under the By-laws by their retirement they will lose the privileges of malpractice defense and Group Insurance and the JOURNAL and Directory, and that they need not accept retired membership if they do not choose and may, by retaining active membership in the Society, continue to receive the privileges of membership. I make that as a motion.

DR. PHILLIPS, of New York: I accept the amendment.

THE SPEAKER: Motion before the House is that the names called by the Secretary this afternoon be voted upon for retirement, that they be notified they need not accept that retirement unless they so desire.

THE SECRETARY: Does that mean that the secretary is going over the heads of the County Societies in regard to these members? The County Societies have retired them.

THE SPEAKER: The Chair rules that if the motion is passed it will force the Secretary to go over the County Societies' heads; if the motion is lost the matter is still before you in the original form for the retirement as it has always been.

THE SPEAKER: Those in favor of the motion made by Dr. Rooney and accepted by the original mover, signify by saying aye.

Motion made, seconded, and carried.

THE SPEAKER: The next order of business before the House will be the report of the Chairman of Reference Committee A.

70. RACIAL DISCRIMINATION

Section 30

DR. PODVIN, of Bronx: This is the resolution read by Dr. Leitner near the close of the session in relation to the conditions in Germany in the profession, and the abuses there.

Your committee approves the resolution and moves its adoption.

Seconded and carried.

DR. HEYD, of New York: When we adjourn tonight I would move that we reconvene this House tomorrow morning at nine o'clock. It is essential that a large delegation go from here to Albany to oppose the osteopathic bill and it would be rather harmful to this House to have absentees when there is an election pending or in course of being decided. I therefore, move that it be the order of the day for this House to reconvene at 9 A. M. tomorrow.

THE SPEAKER: And that the first business be the election of officers.

Motion seconded and carried.

THE SPEAKER: The next order of business before the House will be the report of the Reference Committee on Economics.

71. REPORT OF REFERENCE COMMITTEE ON THE REPORT OF THE COMMITTEE ON ECONOMICS

Section 29

DR. ROONEY: Gentlemen of the House of Delegates: I shall move the adoption of this report paragraph by paragraph.

"Your committee has carefully reviewed the report of the Committee on Economics and desires to commend their painstaking work as evidenced therein. The brevity of the report

has greatly facilitated the deliberations of your Reference Committee

The Committee on Economics has made no specific recommendations as such your Reference Committee, however, has felt it desirable to make certain changes in the language and to add of its own initiative a few recommendations for the consideration of the House. Practically all of the report is informative, much of which describes the continuation of the work of last year's Committee and the pursuance of the direction of last year's House

Paragraph one, no change

1 The study and work needed to quickly develop the economics of Medical Service with justice to all requires vast expenditure of time and funds. We have used our endowment of both in an earnest effort to accomplish the maximum possible, over the period of three years during which the Committee has served you in (majority) continuity. The first report (1932) sketched the fields of endeavor which called for study, readjustment, and reform and contained many recommendations calculated to arouse expression of thought and opinion among the membership of the State Society. Many recommendations were adopted, more were referred for further study (most desirable) and a few were rejected. The second report concerned the development of a few projects of surpassing importance, the Workmen's Compensation Law, the Public Welfare Law, the Public Health Council, promotion of preventive medicine, General Municipal Law and its amendments, Veterans' Administration Hospitals, the financing of sickness, physicians and the courts, and an amendment to the Lien Law to protect hospitals, nurses and physicians from exploitation in accident cases. With wise and helpful amendments the recommendations upon these matters were adopted by your House

I move its adoption

DR. ROONEY I will make a further motion in order to save time, and that is that I will move the adoption of each paragraph and the Speaker will so rule unless there is an objection from the floor. We will not have to put each paragraph to a vote unless there is an objection, the paragraph will be held as approved by the House. I make that motion

Seconded and carried

DR. ROONEY Paragraph two. In the third sentence of this paragraph we recommend the interpolation of the word 'County' between the words 'organization' and 'and the deletion of the word 'departments'

2. Thus the third report, offers for your parliamentary review a few matters only. The year's work has been undertaken with the aim to bring to earliest possible cooperative or legislative completion certain important projects. This can only be done after prolonged conferences between representatives of various organizations, County and State. It is clear to us that reform in hospital economics can best be planned by conferences and agreements between subcommittees of hospital officials and representatives of the County and State Societies. Also improved legislation can be facilitated by conference with State Public Health and Public Welfare officials. What the State Medical Society alone recommends may take years to filter through various official political and legislative media, if ever. With united opinion of

the Society and State Departments reforms may be prompt and conclusive. Most of our year's work has proceeded upon these principles. This report, largely informative, deals with unfinished work undertaken with enthusiasm, and developed to a point where faith in the principle of cooperation seems justified

I move its adoption

Seconded and carried

DR. ROONEY Paragraph three. In view of the fact that the Bill on Workmen's Compensation introduced this year died in committee, it is recommended that steps be taken to reintroduce the Bill during the next session of the Legislature. We recommend that there be a conference between the members of the State Society, who served on the Governor's Commission with representatives of the Committee on Economics and Legislative Committee with a view of taking advantage of the experience gained during the hearings on the Bill so as to present a more satisfactory Bill for introduction in the Legislature of 1934 and to take steps toward its enactment

I move its adoption

Seconded and carried

DR. ROONEY Paragraph four no change

4 *Economics of Hospitalization*—In regard to the re-referred matters under this caption and others in all of which this Committee was to share responsibility with other Standing Committees progress has been made. Our subcommittees were appointed early in the year. After several meetings of the Standing Committee Chairmen with our President, the primary consideration of these subjects were assigned to subcommittees from the various Standing Committees to facilitate action. (This keeps traveling and meeting expenses at lowest possible total). In January at the meeting of Chairmen of Standing Committees our Committee was asked to prepare agenda for these conferences of subcommittees. These have been prepared, reviewed by our complete committee in meeting, mimeographed and were forwarded to the Standing Committee Chairmen in February. In all probability some of the conferences will have been held before the session of the House of Delegates convenes

I move its adoption

Seconded and carried

DR. ROONEY Paragraph five, no change

5 In general the Committee reaffirms its views concerning the Economics of Hospitalization excepting those paragraphs disapproved by the Reference Committee and the House of Delegates. Some of these have interested Hospital Directors and Superintendents and are being considered at joint conferences with the Committee of the State Hospital Association reported in paragraph 6 of this report

I move its adoption

Seconded and carried

DR. ROONEY Paragraph six no change

6 Interest in the Evans and Crawford Bills of 1933 and in the State Medical Society's approval thereof led the then President of the State Hospital Association to request informal conference with representatives of our Committee. Here it was agreed that if the representatives of hospital administration and of organized medicine could meet discuss and agree upon a solution of any of the problems of mutual interest it would be possible to put cor-

rective measures into effect without delay or the necessity of action by the legislature. Or, should the latter be necessary, that having established agreement, we could jointly support it at Albany. The first informal meeting occurred in July. In November an officially appointed group met our Committee. The following topics were discussed:

Definition of indigency—in relation to medical care.

Principle: The indigent is the ward of the community.

Indigent should pay no fees.

Beds for free hospital care—reserved for indigents.

Hospital rates adjusted to eliminate deficits.

No corporate practice of medicine by hospitals.

Hospital insurance to cover hospital service, not medical care.

Subcommittees were appointed to study the economics of hospital relationship to the practice of:

Anesthesia.

Pathology.

Roentgenology.

Physical therapy.

House obstetrics, and other unit fee schemes.

The subcommittees are actively engaged with their respective problems. As soon as they are ready to report, another joint conference will be called. The State Medical Society and the State Hospital Association will make final disposition of these matters when subcommittee and joint committee actions are reported to them. Subcommittees have met and report progress. Joint committee action may be expected in May or June.

I move its adoption.

Seconded and carried.

DR. ROONEY: Paragraph seven. No change.

7. In the meantime local units and groups have taken up consideration of the problems in the Economics of Hospitalization. We appreciate that there is constantly a local complexion to such problems. However, the fundamental principles are essentially the same over the State. In Monroe County (including Rochester) a plan of clinic admission control is reported to be working effectively. Erie County has a plan of control. In the Metropolitan area representatives and hospital administrations are conferring on the problem of clinic control and related topics. General agreement has been reached that patients seeking free medical clinic care shall be required to make a financial statement. Some hospitals have put this into effect without waiting for a general official adoption. One institution reports a 10 per cent drop in clinic attendance for the first month. Bronx County investigated one thousand consecutive admissions and demonstrated that only about 48 per cent were justly entitled to free care. Westchester County calculated the value of free care for one year. Based on moderate fees and prorated to the staff members it indicated that each one had donated the equivalent of \$4,400 to the care of hospital patients. In Ontario County the Society contracted with the authorities for a fixed sum to do all county cases. After two years this has been abandoned and they now insist upon a return to a fee-for-service plan. Suffolk County continues its outstanding position in the solution of the care of the poor.

In other states experiments are in progress. Notable work has been done in Philadelphia. The outstanding principle of their activity is that no institution shall share in a fee for a service which only a duly licensed physician can render. In St. Louis a *sworn statement* of finances has been required of all patients soliciting free medical care with a result that free-care cases have dropped about 60 per cent. In Battle Creek, an organization of dentists and physicians, membership open to all licensees, contracted to care for the poor of that city for \$12,000 and the administration costs of the plan amounted to \$1,600 for the disbursement of the first \$6,000—an example of the costs of lay administration.

The details of all these and a considerable number of others are being accumulated and analyzed by your Committee. Out of the experiences of these *trial and error* experiments should come the understanding of principles upon which a planned medical care may be established. It would seem to be the function of this Committee to make contact with and correlate these various activities.

I move its adoption.

Seconded and carried.

DR. ROONEY: Paragraph eight. In the last sentence of the first paragraph after the word "recognized" add "and successfully put into practice in Detroit and recently in Albany." The paragraph will then read as follows:

8. *Public Health*.—General practitioners of medicine should be the chief guardians of the public health, and no town, city, state or federal program can be complete and efficient without participation of all licensed physicians and utilization of facilities established and made available by them. Outstanding results are on record where this has been recognized and successfully put into practice in Detroit and recently in Albany.

I move its adoption.

Seconded and carried.

DR. ROONEY: Paragraph nine. No change.

9. *Medical Care of the Indigent*.—We are striving toward the day when provision for the indigent shall be complete and efficient. These persons and families, while indigent, should pay no fees. They should be wards of the community as represented by organized government in village, town, city, county, state or Nation (in order of responsibility). Although indigent they should be accorded the same *free choice* of physicians as other citizens possess. It is the duty and the privilege of all physicians to share in the care of the indigent. The cooperation of the County Medical Society with governmental officers in providing medical service for the indigent is very necessary. This function includes regulation of conduct and of remuneration.

I move its adoption.

Seconded and carried.

DR. ROONEY: Paragraph ten. Fourth line after the word "in" insert the word "the".

On the seventeenth line eliminate word "elimination," add in its place "exemption now existing." On the nineteenth line, instead of the words "is imperative" add the words "should be repealed." We approve this chapter and strongly recommend that the necessary steps be taken to abolish the above provisions from the present New York City Charter. The paragraph will then read as follows:

10. The financial obligations of the community recognizing these principles (paragraph 9) are considerable, but could largely be met by abolishing extravagance in the hospitalization and free care of solvent persons. Competent medical care at home is often less costly than hospitalization. Care in private general hospitals in large cities (notably in the Metropolitan area) could be secured at less cost than is obtained in the conduct of city hospitals. Germane to this proposition is the urgent need of extending the operation of the Public Welfare Law of the State to the Greater City of New York. In accordance with our recommendation of 1933 (approved by House of Delegates) the exemption now existing of the Home Rule Law welfare provisions of the City Charter should be repealed. This would make many embarrassed private hospitals more nearly solvent and relieve physicians of an unjust burden of charity which should be carried by the community. Moreover, it would render unnecessary any additional hospital accommodations in city hospitals. The desirability of State Society action aiming to accomplish this needed reform in the new Charter of New York City has been urgently presented to the Executive Committee.

I move its adoption.

Seconded and carried.

DR. ROONEY: Paragraph eleven. We recommend a revision in this chapter as follows:

"The persons and families just above indigency present a problem of special importance. This group is frequently referred to as the white-collared class. Confident and complete medical service is already available to most of these people in most communities. They are liberally provided with most of the luxuries of modern life, but it is stated by many people interested in social welfare that this group cannot afford adequate medical service. Committee believes that these statements are largely exaggerated. However, the problem facing organized medicine is to provide through the services of private practitioners and specialists adequate medical service at a cost within the individual's capacity to pay. Where the ordinary fees for medical services are beyond the immediate possibility of the person or family to meet them, it should become the duty of the profession through the local County Unit to meet the situation by cooperation with the practicing physicians of the community. We recommend the advisability of setting up County Society information bureaus for the direction of such patient to private practitioners and specialists. We believe that while periodic health examinations should be recommended within reason and particularly for the purpose of instituting known preventive procedure and especially in the early age and adolescent group, we feel that the so-called periodic health examination campaigns have often promised more than they could accomplish and add unduly to the cost of medical care. Interested parties have pointed to this procedure as an evidence of the fact that this group in a community is not receiving adequate medical care, whereas the benefits of periodic health examinations have been largely exaggerated."

I move its adoption.

Seconded and carried.

DR. ROONEY: Paragraph twelve. Approved and it is recommended that this work be continued.

12. Early in the year it was recognized that if the principles presented in paragraphs 8, 9 and 10 were to be brought to fruition in any considerable degree general cooperation of our Society, State governmental departments, and welfare agencies must be obtained. It was also in our records that there was a lack of harmony in the various laws which contain provisions for the care of the indigent. At a conference of State Society officials, State Department Commissioners and charity directors, and members of our committee, the following procedure was planned:

(a) The physical assembly of operative laws having to do with the care of the indigent excluding those dealing with custodial care. (State Commissioner Adie of the Social Welfare Department is providing a research worker for this work.)

(b) The assembling of these into an interleaved pamphlet by our Committee, this pamphlet to be distributed to the officers of this Society, to the officers of State Departments and the charitable organizations for opinion, comment and suggestion as to elimination of faults and introduction of improvements to the end that all laws concerning the care of the indigent shall read identically and to provide efficiently against misunderstandings, maladministration, and abuses. Moreover, it is our hope that in this way the principles presented in paragraphs 8, 9 and 10 can become a part of all of these laws.

(c) All suggestions are then to be formally considered by the officials of State Departments, Welfare organizations and State Medical Society officials and agreement upon needed new legislation secured.

(d) We have the assurances of Commissioners Parran and Adie that when the work is complete, means will be found to publish, in manual form, a single volume which will contain all of the regulations as a guide for the information of those who are charged with the administration and of those who render medical care to the poor.

While this is undertaking a long and very responsible task, we believe that ultimately an admirable service to the people and justice to the physicians of the State will result. Much of the material is already in hand. We hope to have the first copy of the pamphlet edited and in circulation before July 1st. Progress onward to the completed printed edition will depend upon the receipt of returned comments.

I move its adoption.

Seconded and carried.

DR. ROONEY: Paragraph thirteen. Line twelve—delete the word "dole" and add the word "provision."

In the 21st line, new sentence should read "The State through the agency of local authority is, we believe, wrongfully assuming too large a responsibility in individualized service. In the 17th line after the words "potent efforts" add the words "by the foundations and other interests." The paragraph will then read as follows:

13. *The Medical Care Needs of the Indigent.*—On the one hand, your Committee is aware of a growing volume of complaint that our profession cannot further carry the burden of *free medical care* and of the increasing exploitation

of the traditional charitable practices of our profession. There is a demand for some reasonable compensation for the service which the physician renders for the general good of the community and the exercise of a more strict control of the provision of free care. On the other hand, not a few fear that compensation for the care of the poor will be only a first step to socialization of medicine with its inevitable breakdown of standards. Potent efforts by the foundations and other interests to shape public opinion to some program of planned medical care for the poor and near-poor are obvious and pertinent to the economics of medicine. The State through the agency of local authority is, we believe, wrongfully assuming too large a responsibility in individualized service; while other influences would lead us into the pitfalls of some scheme of *compulsory health insurance*. Volunteer agencies offering free clinic and bed care to the sick are generally in financial distress. The way out of this complex situation is not evident. Your committee has undertaken to collect and put informational matter in proper order. No definite recommendation is possible from the data now in hand.

I move its adoption.

Seconded and carried.

DR. ROONEY: Paragraph fourteen. Delete everything after the words "STATE JOURNAL" in the 5th line. In explanation, it has nothing to do with anything except the workers in industry, particularly in relation to the A. & P. who have maintained their medical staff. They have a chief of medical service who acts simply as director of this service. Yet an employee of the A. & P. is injured in Oshkosh, Michigan, he communicates with the Director of Medical Service, and if that employee is receiving, in the opinion of the Director of Medical Service, incompetent treatment, he changes the case from that man to some other man who is competent. The A. & P. and certain of the other industries have maintained the service during the depression without any further cuts in their medical personnel, either in number or in money. This is entirely comparable with the reductions that have had to be made in all of these corporations with all their other executives.

Your committee felt that this was simply an isolated instance. It was not general and for that very reason we should delete everything about it, and that is why the recommendation of the committee is to delete everything after the word "STATE JOURNAL."

The paragraph will then read as follows:

14. *Medicine in Industry*.—Our subcommittee has submitted an adequate report of its survey during the year which has been offered for publication in the STATE JOURNAL.

I move its adoption.

Seconded and carried.

DR. ROONEY: Paragraph fifteen. No change.

15. *Practice of Medicine by Corporations*.—(a) Our subcommittee has reviewed varying situations in this State and elsewhere. Their report is elaborate and most interesting and has been presented for publication in the STATE JOURNAL. Hitherto undiscussed points are raised in this report and a clearer understanding of the actual facts may be had by studying this article when published.

(b) The Counsel of the Society, Mr. Brosnan,

has written a valuable opinion on the subject of the practice of medicine by corporations. This will be published in the STATE JOURNAL at an early date.

I move its adoption.

Dr. Rosenthal commented on the fact that no action had been taken on the matter of corporations practicing medicine.

DR. ROONEY: Your reference committee was a reference committee appointed to consider solely the matter referred to in the report of the Committee on Economics. We have no right to go outside of that report and express our opinion on anything except that which is germane to it.

Motion was seconded and carried.

DR. GOODRICH: Dr. Rosenthal's remarks undoubtedly impressed some of the members of this House who perhaps did not recall that a year ago the committee recommended that the Attorney-General bring suit against some corporations for practicing. That was in the hands of the Executive Committee and ourselves and we felt that on their action we could rely and therefore there was no attempt to make further recommendations along that line although we believe, just as Dr. Rosenthal does and just as the executive committee does.

DR. ROONEY: I understand that another resolution will be introduced tonight or tomorrow morning in relation to this matter.

Paragraph sixteen. The 6th line "rediscout" instead of "discount." The paragraph will then read as follows:

16. *Financing Sickness*.—We have, in accord with instructions, continued this study. We are encouraged to believe that when the banking industry has become less apprehensive of the general economic conditions, some plan of rediscount facilities will be arranged for handling large credits of medical care. This is the crux of the problem. Many collection agencies and discount companies continue their practice of frauds.

We have specifications of *standards* and a *provisional* program for the control of these affairs. The establishment of a list of *accepted* firms entails certain costs of administration. When the money to cover the expense is provided, we shall put our plans into effect.

We recommend that this study be continued.

I move its adoption.

Seconded and carried.

DR. ROONEY: Paragraph seventeen. Your Committee recommends that the work suggested in this paragraph be undertaken and that the question of an appropriation for same be referred to Council.

17. *The Cost Analysis of Medical Practice*.—No detailed or extended work (urgently needed) has been undertaken this year because it has been deemed wise to avoid the necessary expenditure at this time.

I move its adoption.

Seconded and carried.

DR. ROONEY: Paragraph eighteen. Approved with no changes.

18. This committee assisted the 140 A. M. A. *Approved Roentgenologists* of the Metropolitan area in the complete organization of its group.

The New York Society of A. M. A. *Approved Roentgenologists* is now committed to the economic problems of this specialty practice, to

encourage higher standards of conduct and to combat those tendencies which may demoralize such standards

The by-laws of this organization prescribe 'The acceptance of membership automatically waives any and all rights to claim based on any disciplinary procedure on the part of the Society or its officers, for libel and/or slander against any or all members of the Society', indicating that this Society is set up for the purpose of self discipline

I move its adoption

DR ROONEY Paragraph nineteen The first paragraph is approved The second paragraph should be deleted This question is now being considered by other committees and resolutions have already been introduced on this subject before the House

The paragraph will then read as follows

19 Radio—There is no censorship exercised over the advertising programs The public is receiving a vast amount of misinformation Self diagnosis and self treatment are encouraged and health habits and regulations of questionable virtue are being promulgated The public health aspect of this belongs to another committee The economic implications are fundamental and considerable

I move its adoption

Seconded and carried

DR ROONEY Paragraph twenty No change 20 Acknowledgment is hereby made of the regular receipt of the following publications and communications, by the Economics Committee

(1) Bulletins from Legislative Committee, Medical Society of the State of New York, relative to bills being submitted in Albany

(2) Bulletin of Medical Society of County of Nassau

(3) Westchester County Medical Bulletin, Westchester County Medical Society Monthly Bulletin

(4) Health News, Department of Health, Weekly Bulletins

(5) Social Welfare Bulletin, Department of Social Welfare, Albany, N Y Monthly Bulletin

(6) Detroit Medical News Wayne County Medical Society, New York State Weekly Bulletins

(7) Calhoun County Medical Society Bulletin, Battle Creek, Michigan Occasional Weekly Bulletin

(8) Minutes of the Commission on Medical Economics Philadelphia County Medical Society Philadelphia Pa

(9) Illinois Medical Journal

I move its adoption

Seconded and carried

DR ROONEY Paragraph twenty one No change

21 To each of the component county societies of the State Society all minutes of our Committee's meetings have been forwarded Minutes were supplemented by a series of bulletins We have exchanged minutes with the Economic Committees of other State and County organizations The Committee now has equipment to render such communications in a more acceptable form in so far as mechanical composition is concerned

I move its adoption

Seconded and carried

DR ROONEY I move the adoption of the report of the committee as a whole and as amended

Motion seconded and carried

72 PUBLIC HEALTH COUNCIL

DR. ROONLY Your Committee recommends that the constitution, powers and potentialities of the Public Health Council be referred to the joint consideration of the Committees on Public Health, Public Relations and Economics, with legal counsel for report at the next Annual Meeting of the House

This committee also recommends this joint committee consider the importance that at least two of the three physicians be members of this Society now active in the practice of medicine, and not Public Health officers or employees of the Department of Health and who shall be chosen from a list of not less than thirty recommended to the Governor for such appointment by the President of the Medical Society of the State of New York The purpose of that is this, as the former paragraphs of the report of the Committee on Medical Economics have shown you—paragraph 34—it states Of the six members at least three must be physicians experienced or trained in sanitary science and one must be a sanitary engineer As a matter of fact, under the present law there is but one man, one physician on the Public Health Council at this date who has ever been in the active practice of medicine Now, for a body that has such power your Committee felt that there should be some provision by which a proper representation of the active profession should be on the Public Health Council

I am interested to know what happened to the report made last year referring this most important matter to these joint committees, of which I have heard no report today

DR ELLIOTT, of Kings The chairmen of the committees met and discussed how to undertake this work It was first proposed to bring all the committees together, it was finally agreed that that would be a waste of time and money, and it was finally determined that the Committee on Economics should draw up an agenda for study by a subcommittee That has been done

It is a very large undertaking and we have asked along with the Public Relations, Public Health and Medical Education that we may have your indulgence to give this whole field the time and careful study which it deserves

DR ROONEY This recommendation is specific It says this and this shall be done and a report shall be made at the next meeting of the house It was not a question of whether there is expense or no expense

Now I will move that this matter be referred and report be made to the next meeting of the Council

Motion seconded

DR. FARMER I wonder if the Chairman of the Reference Committee is aware of the fact that this State Society has already made resolutions to that same effect when they accepted the report of the Joint Committee to study the Governor's Health Commission That Committee made a resolution practically covering all of these recommendations and the State Society adopted it So that we are already committed to that program

DR. ROONEY: Do the recommendations of this committee provide that three of them should be active practitioners of medicine, none of whom should be either sanitary or public health officers, or the like?

DR. FARMER: The report is not exactly in those terms, but I think the verbiage is pretty plain. We did state that the appointment should be made from a panel of names submitted by the State Society to the Governor.

DR. ROONEY: May I ask again the question: Does this recommendation state that three of these men shall be active men in the practice of their profession who are neither public health officers or sanitary officers employed by the state?

DR. FARMER: I cannot answer that definitely.

DR. ROONEY: I move that the Committees on Public Health, Public Relations, and Economics, in association with legal counsel of the Society consider this subject and make such recommendations as will provide that this Joint Committee consider the importance of the fact that at least two of the three physicians on the Public Health Council be members of this Society now active in the practice of medicine and not public health officers nor employees of the Department of Health and who shall be chosen from a list of not less than thirty recommended to the Governor for such appointment by the President of the Medical Society of the State of New York. And that they report to the September meeting of the Executive Committee.

DR. SCHIFF, of Clinton: I offer a substitute motion: That in place of referring this matter back to these committees, that it be called to the attention of the Council for action. On the Council are the chairmen of these standing committees and they always have the advantage of consultation with regular counsel, and I believe he would get the action he wants if he would accept that substitution.

DR. GOODRICH, of Kings: I second the motion.

DR. ROONEY: It should be referred to the Committees for action. They are the ones to act. The Council is a deliberative body.

THE SPEAKER: The substitute motion is before you. All those in favor signify in the usual way * * * * all those opposed * * * *. The Chair is in doubt.

THE SPEAKER: Those in favor of the adoption of the substitute motion made by Dr. Schiff will kindly rise * * * *. Those who are opposed to the substitute motion kindly rise * * * *. The chair announces the vote fifty-six in favor and fifty-five opposed. The motion is carried.

THE CHAIRMAN: The substitute motion was carried. That does not dispose of the question because the substitute motion simply referred the matter to the Council.

DR. ROONEY: We have gotten action!

73. RESUSCITATION

Section 68

DR. HAMILTON, of New York: Committee on New Business C approves and recommends the adoption of Dr. James Rooney's resolution in reference to misleading propaganda in reference to resuscitation.

I move its adoption.

Motion seconded and carried.

74. CORPORATIONS PRACTICING MEDICINE

Section 77

DR. ROSENTHAL, of New York: I have a resolution.

RESOLVED, that the House of Delegates request the Council to instruct the Counsel to start suit against the corporations practicing medicine and to determine the legality of such practice.

THE SPEAKER: That resolution will be referred to Committee on New Business C.

75. REPORT OF PRIZE ESSAY COMMITTEE

THE SECRETARY: I have a report from the Prize Essay Committee.

The Committee on Prize Essays of the State Society has received four essays. Each of these has merit. The Committee is unanimous in recommending that the Merrit H. Cash prize be awarded to the author of the essay, entitled "Spontaneous Subarachnoid Hemorrhage and Its Relation to the Aneurysm of the Circle of Willis," by Dr. Wardner D. Ayer of Syracuse.

On motion duly made, seconded, and carried, Dr. Ayer was awarded the prize.

76. AMENDMENT TO BY-LAWS—RETIRED MEMBERS

DR. DOUGHERTY: The following amendment to the By-laws is now presented for action:

Amend Chapter 1, Section 5, of the By-laws by the deletion of the words "and retired," and the addition of a new sentence "retired members shall have all the rights and privileges of active members without assessment."

THE SPEAKER: The amendment will have to lie over for one year.

THE SECRETARY: The following amendment to the By-laws which was introduced at the meeting held in New York City, April 3, 1933, will now be presented for action:

Chapter 8, Section 1. Twenty-sixth line, second paragraph, delete the words "not to exceed \$200.00" and insert: "A sum to be determined on a per capita basis of membership by recommendation of the Executive Committee and final determination by the Board of Trustees."

The sentence will then read: "Each District Branch shall be entitled to receive a sum to be determined on the per capita basis of membership by resolution of the Executive Committee and final determination by the Board of Trustees."

Amendment seconded.

THE SPEAKER: It is necessary for this amendment in order to prevail, to have a two-thirds majority on a vote. Those in favor of the amendment will rise; those opposed to the amendment will rise. The amendment is lost.

THE SPEAKER: Is Committee C ready to report on the resolution of Dr. Rosenthal?

77. CORPORATIONS PRACTICING MEDICINE

Section 74

DR. HAMILTON, of New York: The resolution offered by Dr. Rosenthal, that the House of Delegates request the Council to instruct Counsel to start suit against a corporation practicing medicine to determine the legality of such practice, is disapproved, and recommends that the pledge given to the House of Delegates in 1931 by Dr. Harold Rypins, Secretary of the

State Board of Medical Examiners, that if, and when the Medical Society of the State of New York furnished him a brief against the Life Extension Institute, that he would exercise all diligence to have the Attorney-General bring such suit. This brief was delivered to Dr Rupins in 1931, and

Recommends that the Secretary be instructed to communicate with Dr Rypins, requesting information as to the status of the proposed suit.

If such suit had not been instituted, it is recommended, that instructions be issued to the Executive Committee, that they request the Attorney-General to bring such suit.

I move its adoption.

Motion seconded.

THE SPEAKER Those in favor of the adoption of the Report of Reference Committee on New Business C on the resolution of Dr Rosenthal, signify in the usual manner, those opposed, motion carried.

THE SPEAKER Is there any further business to come before this House?

DR ROONEY, of Albany I move that this House now adjourn and that it reconvene tomorrow morning at nine o'clock.

The meeting therefore adjourned until Tuesday, May 15th, at 9 A. M.

ADJOURNED SESSION OF THE HOUSE OF DELEGATES

Tuesday, May 15th, 1934

The meeting was called to order by the Speaker at 9 00 A. M.

78 ROLL CALL

THE SPEAKER The first order of business will be the roll call.

The Assistant Secretary called the roll and the following delegates responded.

Frederic C Conway, William P Howard, Edgar A Vander Veer, Lyman C Lewis, J. Lewis Amster, William Klein, Edward R. Cunniffe, Louis A. Friedman, Vincent S Hayward, Jacob A Keller, Moses H Krakow, Edward C Podvin, Howard W Davis, George C Vogt, Joseph P Garen, Harry S Bull, Walter G Hayward, DeForest W. Buckmaster, Reeve B Howland, Earl W Wilcox, Leo F Schiff, Louis Van Hoesen, Charles J Kelley, Robert Brittan, Samuel E Appel, William A Krieger, Aaron Sobel, George R. Critchlow, Robert E De Ceu, Harold F Brown, John T Donovan, Albert A Gartner, Edward C. Koenig, Thurber Le Win, Edward A Sharp, Harold J Harris, Charles C Trembley, Sylvester C Clemans, George L Branch, Cecil C. Whittemore, Murray M Gardner, Robert F Barber, John L. Bauer, Alec N Thomson, Thomas M Brennan, Donald L. McKenna, Cassius H Watson, Simon Frucht, Charles H Goodrich, Charles T Graham-Rogers, Edwin A Griffin, John E Jennings, Henry Joachim, Walter D Ludlum, Thomas A. McGoldrick, John J Masterson, Sydney Nussbaum, Joseph Raphael, J Sturdivant Read, Paul E Wesenberg, Alfred E Shipley, James Steele, Luther F Warren, Nunzio A Rini, F Edward Jones, Gerald E. Murphy, George S Pixley, Clarence V. Costello, William A MacVay, Willard H Veeder, Edward T Wentworth, Warren Wooden, Horace M Hicks, James W Bulmer, Everett C. Jessup, Emily D Barringer, Milton A.

Bridges, Walter T Dannreuther, Adolph G. De Sanctis, J Stanley Kenney, Ten Eyck Elmendorf, Julius Ferber, B Wallace Hamilton, David J Kaliski, Samuel M Kaufman, Frederick C Keller, George W Kosmak, Richard Kovacs, Otto H Leber, Jacob Mandel, William M Patterson, Nathan Ratnoff, Morris Rosenthal, Wendell C Phillips, James W Smith, N Thomas Saxl, Terry M Townsend, Franklin Welker, William A Peart, George M Fisher, Charles D Quinn, Andrew Sloan, John J. Buettner, William W Street, Albert G Swift, Homer J Knickerbocker, Joseph B Hulett, Moses A Stivers, Sherman M Burns, Floyd J. Atwell, Carl Boettiger, James M Dobbins, Daniel J Swan, H P Mencken, James R Reuling, Jr., Walter C A Steffen, Stephen H Curtis, Augustus J Hambrook, Oscar M Race, Eugene D Scala, George A Leitner, W Grant Cooper, Stanley W Sayer, George S Towne, Dudley R Kathian, William C Treder, David W Beard, Frederick W Lester, Leon M Kysor, Herbert B Smith, Albert E Payne, Luther C Payne, Guy S Carpenter, Wilber G Fish, Frederic W Holcomb, Morris Maslon, Denver M Vickers, Ralph Sheldon, William J Doerfler, Robert B Hammond, Arthur F Heyl, Fred Brillinger, Romeo Roberto, George G Davis, Bernard S Strait.

The following Officers, Trustees, and Chairmen of Standing Committees were present.

Frederick H Flaherty, Arthur J Bedell, Ralph R. Fitch, Daniel S Dougherty, Peter Irving, Frederic E Sondern, Samuel J Kopetzky, Floyd S Winslow, Nathan B Van Etten, Grant C Madill, Harry R Trick, James F Rooney, George W Cottis, William A Groat, Thomas P. Farmer, Harry Aranow, Frederic E Elliott, James E Sadlier, Andrew Sloan, C Knight Deyo, Louis A Van Kleck, Clark G Rossman, Raymond G Perkins, Edward R Evans, Stuart B. Blakely, James M Flynn.

The following Ex Presidents were present: Charles Stover, Wendell C Phillips, Martin B Tinker, Thomas H Halsted, Grant C Madill, J Richard Kevin, James F Rooney, Arthur W Booth, Orrin Sage Wightman, Nathan B Van Etten, George M Fisher, James E. Sadlier, Harry R. Trick, James M Vander Veer, William H Ross, William D Johnson, Chas Gordon Heyd.

79 TELLERS

THE SPEAKER There being a quorum present, the next order of business is the election of Officers.

The Secretary announced the tellers.

Frederick C Keller, William P Howard, James W Smith, Luther C Payne, Willard H Veeder, H P Mencken, Robert F Barber, James M Flynn, Luther F Warren, N Thomas Saxl, Harry S Bull.

80 ELECTION OF OFFICERS

The following officers were nominated and elected.

President elect, Frederic E Sondern, First Vice president, Andrew Sloan, Second Vice-president, Leon M Kysor, Secretary, Daniel S Dougherty, Assistant Secretary, Peter Irving; Treasurer, Charles H Goodrich, Assistant Treasurer, George W Kosmak, Trustee, Nathan B Van Fitten, Speaker, Samuel J Kopetzky; Vice-Speaker, Floyd S Winslow, Chairman of

Committee on Legislation, Harry Aranow; Chairman of Committee on Public Health and Medical Education, Thomas P. Farmer; Chairman of Committee on Economics, Frederic E. Elliott; Chairman of Committee on Public Relations, James E. Sadlier.

The following were elected Delegates to the American Medical Association for 1935-1936:

Drs. Edward R. Cunniffe, Thomas P. Farmer, Floyd S. Winslow, Arthur J. Bedell, William D. Johnson, Grant C. Madill, James F. Rooney, Terry M. Townsend, Frederick H. Flaherty, J. Richard Kevin.

The following were elected Alternates to the American Medical Association:

Thomas M. Brennan, Samuel J. Kopetzky, Harry R. Trick, Carl Boettiger, Louis A. Van Kleeck, George R. Critchlow, Emily D. Barringer, Julius Ferber, Andrew A. Eggston, James R. Reuling, Jr.

THE SPEAKER: Is there any other business come before the House?

81. PRESENT STATE ASSESSMENT CONTINUED

DR. ROONEY, of Albany: I move that present state assessment be continued for ensuing year.

Motion seconded and carried.

DR. BEDELL, of Albany: I move a rising of thanks in expression of our appreciation of courtesies extended us by our hosts, the Medical Profession of Utica, and the surrounding cities, the City Management, and to the ladies of the Organization.

Motion seconded and carried.

DR. ROONEY, of Albany: I move that House now adjourn sine die.

Motion seconded and carried.

Samuel J. Kopetzky, *Speaker*
Daniel S. Dougherty, *Secretary*

THE DOCTOR AND THE DEPRESSION

An investigation by *Medical Economics* seems to show that the average annual net income of the physicians has declined from \$5,806 in 1928 to \$3,969 at the present time, a falling off of 32 per cent. The figures were reached by averaging the 4,223 replies to a questionnaire sent out to all parts of the United States to large and small cities and towns and agricultural areas. The net income is calculated to be about 61 per cent of the gross income, so that the average gross income would thus be about \$6,500 a year.

It is figured, too, that the more prosperous half of the medical profession get three-fourths of the total net income. That is to say, if the total net income of the entire American medical profession is \$508,032,000 per year, then the upper half of

the list of doctors get \$381,024,000 of it and the poorer half get only \$127,008,000, or an average of \$2,122 per year. The average of the half would be \$5,812 each.

A decline of 32 per cent in net income seem large, but does not look so bad when realized that many of our largest corporations have seen their net incomes vanish entirely turn into net losses during the depression. Many of them are feeling very cheerful over the fact that they are not as deep in the red as last year. Corporations whose net income is only 3 per cent below 1928, are considered fortunate, and may easily happen that the physicians will return to normalcy earlier than their friends in the business world.

A Summer Drive for Child Health

Disease takes no vacations, and it is a brilliant stroke of strategy of the National Congress of Parents and Teachers to use our summer vacation months for a determined and vigorous drive for child health. That is a vast improvement over using them merely for play, relaxation, and genteel loafing. These are the months when the little folks are out in the fresh air and sunshine, exercising every muscle in outdoor games, and exercising their lungs in shrieks and yells that torture the nerves and sour the tempers of all the old ladies within earshot.

All this will help put them in splendid shape to start the long pull of the school year in the fall, but more yet is needed. Many of the boys and girls have defects that need correction, and health examinations should be made early in the summer, to give plenty of time for treatment. The aim of the drive is to have every child's health as near perfect as possible when school opens. The local parent-teacher organization should work hand in hand with the doctors to see that every child is carefully looked over and all medical and dental defects taken care of.

Protection against diphtheria and small-pox are, of course, imperative, yet some

parents are so ignorant or careless as to pay no attention to it. Here is where the local health officer and the parent-teachers association can work together in locating children who have not been immunized and seeing that they are given protection. Educational measures to teach the parents what should be done will be timely.

The point is well made by the State Department of Health that waste motion and futile effort will be avoided if the health-officer, the school and the parent-teachers association work together in this drive. Separate efforts will be more or less disorganized, haphazard, and duplicated. There will be an inevitable tendency to "let George do it," and nothing will be done. What is wanted is "the long pull, the strong pull, and the pull all together." Work to improve the health figures for 1935 must begin in 1934.

The Tide is Rising

The tide of public concern over the deaths of mothers in childbirth is rising higher and higher. The matter is being taken up, not only by medical societies, nursing organizations, and women's clubs, but by American Legion posts and Rotary, Kiwanis, and Lions clubs, for the fathers are naturally and rightly aroused when the mothers' lives are in danger.

The N. Y. Academy of Medicine certainly "started something" by its famous report, and although a storm of criticism has assailed it, the facts have not been denied, and it is supported by findings of the British Maternity Commission, The New York State Department of Health, the Federal Childrens' Bureau, and other nonprejudiced investigators.

Still more facts, indeed, emerge as the discussion goes on. For instance, Dr. Thomas J. Parran, Jr., New York State Commissioner of Health, points out that while the loss of mothers' lives is deplorable enough, the infant deaths outnumber them many times over. Thus last year in this state 1,168 mothers died in childbirth, but more than 3,000 babies died in their first day of life and another 3,000 died in their first month. Think, too, of the homes left motherless and the children left to

run the streets and turn to idleness or crime as the result of maternal mortality, and we have here a black page in our boasted civilization.

Dr. Parran's remedy would be to pay from the public treasury the entire medical, hospital, and nursing costs of childbearing for every woman unable to provide it for herself. He would permit her to pick her own doctor, provided he is competent. This plan has been scored by some as smacking too much of state medicine, and perhaps they are right, but, if so, the critics should propose something better, for any plan, good or poor, cannot be beaten by no plan.

Dr. Howard W. Haggard would awaken everybody to the gravity of the crisis, and get them all busy. He sears with sarcasm the futile sentimentality that sends flowers to the mothers and does nothing to save their lives when their hour comes. It is "a hypocritical gesture," he exclaims, "typical of a people who believe that they can replace a deep obligation by a shallow sentimental flourish!" Meantime 16,000 women in the United States give their lives to maternity every year, "ten thousand of them needlessly—last year, this year, next year, ten thousand lives sacrificed!"

The doctors are already aroused to the tragic situation; Dr. Haggard would also call upon the educators. We educate the coming men and women along many lines that they will never use, but nearly all of them will be parents, and we give them no education at all in parentage. The educator is not to blame; he teaches what the public demands; but he should now rise to the crisis and help change the curriculum to prepare the future home makers to make the homes safe for motherhood. Next Dr. Haggard would summon the mothers whose daughters are expecting children. He declares that one-third of the preventable deaths in maternity are due to failure of the women to avail themselves of facilities that are theirs for the asking. No one has told them. Here is where their mothers have failed. The press has failed, too, in its silence and indifference. On a sinking ship it is "women and children first"; but at home, on land, it is a different story. Chivalry is extinct. Finally, Dr.

Haggard would call upon "Mr. Everyman," the citizen on the street, in the store, the office, the factory, the husband, the father, and, when the worst happens, the widower. He votes for the men who make the laws and enforce them; now let him find out what these authorities are doing to save the lives of the mothers and children of the community. Is care provided for mothers who cannot pay? Are the clinics and hospitals adequate? Is there a competent nursing service? If Mr. Everyman gets busy with a sharp stick, we may be sure that matters will soon be set right.

So the tide rises. Dr. Parran and Dr. Haggard gave their views at a Mother's Day luncheon in New York City, but this vital subject is being discussed all over the land, from the Atlantic to the Pacific, and, as the old saying reminds us, "the rising tide lifts all the ships." It is resistless. Nothing can stop it. It is to be hoped that as the result of all this agitation, the figures on maternal mortality will reveal a great improvement in the not too distant future.

We Move in the "Best Circle"

If you draw a circle on the map of the United States to include the cities of Rochester and Schenectady in this state, and Hartford, Baltimore and Hackensack, in neighboring states, you will take in all but one of the cities winning the first prizes for their class in the city health contest conducted jointly by the United States Chamber of Commerce and the American Public Health Association. The lone prize winner outside the circle is Palo Alto, far off in California, which takes the prize for cities under 20,000 population. Our own city of Watertown gets honorable mention among cities of 20,000 to 50,000, where Hackensack receives the first award.

Here we have revenge at last for the story of the California town which laid out a beautiful cemetery and had to send east for corpses because California was so healthy. Here we have proof in "cold figures" of another kind that the east is the really healthy place, while poor California only shows up with a prize winner for cities under 20,000. Readers planning

vacation trips to the coast are given the privilege of clipping this item to produce at the right moment when western acquaintances begin blowing the trumpets too vociferously

Seriously, however, it is more than just good luck or coincidence when a group of cities all in one region carry off the banners in a health contest. It does not merely mean that healthful breezes have blown over them, or that lucky stars have rained beneficent influences upon their housetops. It means that the doctors, the health officers, the nurses, have been faithful, skillful, earnest, unremitting in their warfare with disease and death. It is clear as daylight that we have in this circle a region where medical ability is at a high level, where people enjoy a state of health just a bit better than you will find it anywhere else in our broad land.

The health contest finds in these cities the following outstanding advances

- 1 A sustained intelligent interest in public health, particularly on the part of influential laymen
- 2 An increased interest in, and participation in, preventive medical measures on the part of practicing physicians and dentists
- 3 An increase in the percentage of young children protected against diphtheria
- 4 An improvement in both the quality and safety of milk supplies, particularly through increased tuberculin testing of cows and pasteurization of milk
- 5 A more general acceptance and practice of the principle of having a periodic health examination of both children and adults

Proper Description of New Therapeutic Agents

Occasionally authors of medical articles fail to describe new therapeutic agents in such detailed form as to allow readers to effect exact reproduction for their own use. Such an instance recently occurred in the pages of the JOURNAL, which escaped, through inadvertence, editorial notice.

In the issue of March 1, 1934, Vol 34, No 5, page 196, Dr H A Butman, M D, L J Schultz, Ph D, and L A Van

Kleeck, M D, in their article, entitled "A New Intravenous Therapeutic Agent for the Control of Peptic Ulcer" described the substance used in general terms as a solution which is 'a combination sodium citrate and sodium chloride buffered to correct hydrogen ion concentration with a buffer salt'. The full detailed formula, supplied by the authors, is as follows:

Sodium citrate	50 grams
Sodium chloride	14 grams
Dibasic potassium phosphate	5.48 grams
Doubly distilled water	1 000 grams

This formula is preserved in 20 cc non-soluble Jena glass ampoules. The ampoules and solution are sterilized under a pressure of 35 lbs of steam for 35 minutes. The hydrogen ion concentration is checked either by titration or by the usual colorimetric method and should be 7.9.

Correspondence

Anonymous letters will not be noticed. All communications must carry full name and address of the writer, but these are omitted on request.

Incomplete Bibliography

To the Editor

My attention has been called to the fact that, in the article entitled "A New Intravenous Therapeutic Agent for the Control of Peptic Ulcer" which was submitted by Dr H A Butman, L J Schultz, Ph D, and myself and published in the March 1, 1934 issue of the NEW YORK STATE JOURNAL OF MEDICINE, Vol 34, No 5, no reference was made to two prior publications of Dr L Winfield Kohn on the same subject, "A New Nonsurgical Treatment for Gastric and Duodenal Ulcer—Preliminary Report," *Pennsylvania Medical Journal* October 1932, and "A New Nonsurgical Method of Treatment for Gastric and Duodenal Ulcer," *Medical Journal and Record*, February 1, 1933.

In both of these articles Dr Kohn describes the use of sodium citrate and sodium chloride in solution properly buffered for intravenous use.

It is clear to us that to Dr Kohn should go the credit for the first report of the use of sodium citrate and sodium chloride in solution for intravenous injection for the treatment of peptic ulcer and that our report should be considered in the light of further experience along the same line.

We regret any embarrassment that this omission may have caused those in charge of the publication of the JOURNAL.

Committee on Legislation

Special Bulletin, May 23, 1934

"MEMORANDUM filed with Assembly Bill Introductory Number 2118, Printed Number 2443, entitled:

'AN ACT to amend the education law, in relation to practice of osteopathy.'

NOT APPROVED

This bill eliminates the present requirement of the Education Law that an osteopath 'shall not perform surgery with the use of instruments' and adds a number of provisions which seem to authorize osteopaths to engage in every form of medical practice except the giving of drugs by mouth to cure disease and the performance of certain specified surgical operations.

This bill is objectionable too, because it contains vague, indefinite and unintelligible language. I refer specifically to the authority which it would convey to osteopaths 'to use those agencies incidental to the care of the diseases included in the examinations of the Board of Medical Examiners.' The Department of Education states that because of ambiguous language it would be

impossible to restrict and prevent any type of medical practice other than some types of major surgery.

Although the proponents of the bill have argued that the intent is that surgical practice be limited to first aid and minor surgery, no such limitations are explicitly written into the bill.

While some types of major surgery are prohibited, all other forms of surgery would be permitted, including many operations which would require a high degree of skill and extended practice.

I want to make it clear that in vetoing this bill no question is raised as to the substantial value and usefulness of osteopathy. This is generally conceded and recognized. This bill, however, would authorize osteopaths to give various kinds of treatment in which many osteopaths themselves do not claim proficiency since such treatments are very different from the traditional scope of their specialty.

The bill is disapproved.

(signed) *Herbert H. Lehman*

Committee on Public Health and Medical Education

At its meeting on May 10, 1934, the Committee heard the following address by Dr. Arthur W. Bingham, of East Orange, New Jersey, and believed it worthy of the attention of the entire membership.

ORGANIZED MATERNAL WELFARE WORK IN NEW JERSEY

ARTHUR W. BINGHAM, M.D.

Chairman, Maternal Welfare Committee, State Medical Society of New Jersey

Organized maternal welfare work in New Jersey was started in 1923 when the Medical Commission for Maternal Welfare of Essex County, consisting of twelve physicians, was appointed by the County Medical Society. Meetings were held each month at first but later every second month, the detail work being carried on by various committees: prenatal, hospital, educational, follow-up, statistical, and finance.

The prenatal committee organized prenatal Work in every part of Essex County following largely the methods employed by the Maternity Center Association of New York City and the Maternity Center of the Oranges, which had been in operation for two years. Prenatal history cards were printed by the commission and distributed without cost to all physicians in the county who wished to use them.

The hospital committee checked up the work of the hospitals, inducing them to use similar record sheets so that the annual reports would be uniform. An obstetrical report is received each year by this committee from each of the leading hospitals in the county, a few small private hospitals

not cooperating as yet. A summary of three years of these reports was published in the *American Journal of Obstetrics and Gynecology*. Directors of one hospital with 66 cesarean sections out of 900 deliveries and another hospital with 44 sections out of 400 deliveries read these reports with the result that in 1933 there were only 21 sections in the former hospital and 11 in the latter.

The educational committee has attempted to present the idea of better obstetrics to the public as well as to the physicians. Many talks have been given by leading obstetricians and one year a drive for better obstetrics was conducted and an afternoon meeting for women was held.

The follow-up committee investigated every maternal death in Essex County by questionnaire at first, but during the past year a paid investigator has made personal visits, using for reports the same blanks which were used in the survey by the New York Academy of Medicine.

The commission started its work in a small way, gradually developing during the past eleven years as the confidence of

physicians has been gained. The work is financed by the Essex County Medical Society. During the existence of the Maternal Welfare Commission, the uncorrected maternal mortality for Essex County according to the State Board of Health has been reduced from 69 to 44 per 1,000 live births and in Newark from 74 to 45 per 1,000 live births.

As a result of this work in Essex County, a Maternal Welfare Committee was appointed by the State Medical Society two years ago, the object being to organize Maternal Welfare Commissions in every county. This has been accomplished in all but one county and we hope to interest this county before long. The work in some counties is much more advanced than in others, but each county has its problems, and time will be required to get the desired results.

The State Committee meets twice yearly with the members of the various commissions. Reports are heard from each county represented. There is also a talk by some prominent obstetrician. One meeting is held at the time of the State Society meeting at Atlantic City in June and the other in Newark in the winter. On the whole, there has been great interest shown and we have had excellent cooperation.

In New Jersey, much of the obstetrical work is done by general practitioners and any plan to improve obstetrics must include them. This is done by allowing them to attend cases in our best hospitals under supervision and subject to certain rules. At Orange Memorial Hospital, which takes emergency and ambulance cases as well as private cases, seventy general practitioners attended cases in 1933. There were 1,045 deliveries with three maternal deaths and only five cesarean sections. Physicians are expected to follow the regular hospital routines, and the following rules are posted in each delivery room:

Consultation with one of the obstetrical staff is required in all of the following cases:

- a all prolonged labors (24 hours),
- b cases requiring cesarean sections,
- c breech presentations (unless very premature),
- d difficult forceps cases or versions,
- e occiput posterior presentations requiring forceps or version,
- f other complicated cases: eclampsia, placenta praevia, etc.

In some hospitals in the county the rule reads "Consultation must be had with a qualified consultant," giving a little more choice.

If the general practitioners are not allowed to attend cases in our best hospitals, they are obliged to use the private nursing homes or keep the patient at home. In neither of these places do they have any supervision nor is it easy to get consultation without considerable trouble and expense. In the supervised hospital, consultations can be promptly given without charge unless the patient is able to pay a moderate fee.

Therefore, we recommend a sufficient number of beds in Class A hospitals where the general practitioners as well as the obstetricians may take their patients, where their work may be supervised, and where they may have the advantage of consultation in abnormal cases.

(The exact date will be determined later.)

FAITHFUL ARE THE WOUNDS OF A FRIEND

The older practitioners who may be perhaps a bit rusty in their ideas and methods are given a prod with a sharp stick by Dr. Malford W. Thewlis of the *Medical Times*, who goes on, however, to add some helpful advice on how to keep up to date. He thinks in the first place that there are too many "outdated practitioners," and he notices that the young practitioners just fresh from medical school seem to go ahead. Judging from the success of many of these younger men we might take it for granted that the public wants a new deal in medicine. Many of the older practitioners will be forced out of practice because they are outdated. Others will come out

on top because they will study the latest methods and some will even go back to medical school. It wouldn't be a bad idea, Dr. Thewlis suggests, for every practitioner who has been in practice for twenty years to go back to medical school for three or six months. With his years of experience he will be able to grasp the newer methods much quicker than the younger practitioner, when he returns to his practice he will find he can compete with the recent graduate. Patients to-day demand much more than they did formerly: they want thorough examinations, performed with speed, and they want the latest view on every subject they consult you about.

Books

BOOKS RECEIVED

Diet and Personality.—Fitting Food to Type and Environment. By L. Jean Bogert, Ph.D. 12mo. of 223 pages. New York, The Macmillan Company, 1934. Cloth, \$2.00.

In this book the author sets out to classify the dietary needs according to the type of person. To use her words, "A great deal of ill health may be caused by people eating food which is not suited to them." One of the most uncertain features of diet books is that no two books are in agreement as to what constitutes a particular diet. But even if we should discount this phase of dietotherapy, there is the element of self-dieting which is never reliable.

One cannot find fault with this book. It follows the pattern of most popular books on that subject, and will merely serve to enlarge the layman's choice of books without offering him anything particularly distinctive.

EMANUEL KRIMSKY

Combined Text-Book of Obstetrics and Gynecology.—For Students and Medical Practitioners. By J. M. Munro Kerr, and others. Second Edition. Octavo of 1100 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$10.00.

The idea of a combined textbook of obstetrics and gynecology is good, yet of doubtful practical value. This book is big enough, yet it covers each subject in very sketchy fashion. Nothing can take the place of a good textbook on obstetrics—even three volumes of obstetrics and gynecology. For medical students, however, this book may be useful, for only fundamentals are included.

It is curious to find that spermatozoa live three weeks, and that intra-uterine douche tubes and laminaria tents are still advocated and pictured; vaginal douches are advised for subinvolution in the puerperium. All the old obsolete methods of infant resuscitation are graphically described, but there is no mention of the new knowledge of asphyxia. In describing the lower-segment cesarean, only the transverse out of Kerr and Hendry is described. The chapter on prolapse is good.

CHARLES A. GORDON

A System of Clinical Medicine.—Dealing with the diagnosis, prognosis, and treatment of disease for students and practitioners. By Thomas Dixon Savill, M.D. Ninth Edition. Octavo of 1063 pages illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$9.00.

The fact that this is the ninth edition, in itself, speaks for the popularity and importance of this book. The new edition has been rewritten but the general principles observed in the previous volumes plus new and special features have been added. The author has carried on the basic and important fundamentals of teaching that he acquired from such eminent and competent workers as Chacot, Murchison, Bristowe, and Broadbent.

This book, in the opinion of the reviewer, is in the same class as Osler. These are two of the best single volumes on medicine. The author throughout follows our natural clinical history of disease and gradually elaborates on the basis of symptoms and the pathological changes which underlie those symptoms.

H. M. FEINBLATT

Life-Giving Light.—By Charles Sheard, Ph.D. 12mo. of 174 pages, illustrated. Baltimore, Williams & Wilkins Company, 1933. Cloth, \$1.00.

This book, while of only 174 pages, brings together in most readable form the major steps through which biological physics has climbed in its pursuit of knowledge. It takes us from the earliest days of glowing embers to the question of "cold light," and its application in the near future. Modern complicated conceptions of the physics of light are well summarized; and what is most important of all, the data are collected from reliable sources to which reference is made, and one soon learns to put reliance in the statements because it is possible—particularly for the specialist—to check certain portions of the text.

Chapter V, "Making the Invisible Visible" deals with optical glass, the magnifying power of microscopes and telescopes, dark field illumination, the ultra microscope, and the use of the X-ray, etc., in gaining information about electrons and electronic speeds. The reviewer feels that he can not only recommend this work very strongly to ophthalmologists, but also to any intelligent mind interested in the progress of the times.

JOHN N. EVANS

Surgical Clinics of North America.—Published every other month by the W. B. Saunders Company, Philadelphia and London. Per Clinical Year (6 issues). 1933. Cloth, \$16.00; Paper, \$12.00.

VOL. 13, No. 1, FEBRUARY, 1933. (*Pacific Coast Surgical Association Number.*)

In this issue a large number of short papers touching upon all the important questions of surgery have been collected. Interesting case histories as well as short essays are skillfully blended into a complete volume, which is both instructive and absorbing.

VOL. 13, No. 2, APRIL, 1933. (*New York Number.*)

The April issue comes from the hospitals of New York. The Memorial and Mount Sinai Hospitals are represented by many excellent papers of practical value.

Transfusions and their attendant dangers are discussed by R. E. Stetson. Cancer is given a prominent place among the forty contributions. The volume is well illustrated.

VOL. 13, No. 3, JUNE, 1933. (*Lahey Clinic Number.*)

This issue is of importance to every surgeon. Diseases of the thyroid come in for a very thorough discussion. Gastric and intestinal resections are discussed by Lahey himself, in his usual fluid, forceful, and instructive manner. He proposes a scheme in dealing with the proximal jejunum in gastrectomies, which is a radical departure from the accepted methods.

Surgery of the biliary system is discussed by Lahey and Clute. The volume, containing almost three hundred pages, is replete with valuable facts from which both the tyro and expert can profit equally.

VOL. 13, No. 4, AUGUST, 1933. (*Mayo Clinic Number.*)

The Mayo Clinic has been and still is a post-graduate Mecca for many an American surgeon. The thoroughness of the work done at the Clinics, as well as the sound conservative judgment exercised by its Members and Fellows have always been reflected in their publications. This issue is no exception. The articles are concerned with practical problems, problems occurring daily in the practice of the general surgeon.

The presentations are to the point and conclusive. The illustrations are excellent.

VOL. 13, No. 5, OCTOBER, 1933. (*Chicago Number.*)

The Chicago Surgeons have sounded a new note in this issue of the Clinics. They have dedicated most of the articles to the surgery of children; a happy thought. These problems are usually different from adult surgery and an illumination of these standards is very timely. Chicago's best have contributed to the subjects of intracranial tumors, acute mastoiditis, acute empyema, pyloric stenosis, etc. Adult problems are also discussed and substantiated with convincing case histories and illustrations.

VOL. 13, No. 6, DECEMBER, 1933. (*Pacific Coast Number.*)

This issue is edited more like a compendium of case histories than other numbers of this famed series. Among the numerous cases, some of which are extremely rare, we find a wealth of practical information of the more commonly observed surgical problems. This fact makes the issue particularly attractive to the general surgeon in his quest for scientific solutions of the baffling problems he meets in his daily practice.

GEO. WEBB

A Synopsis of Surgery.—By Ernest W. Hey Groves, Tenth Edition. 16mo. of 693 pages. Baltimore, William Wood & Company, 1933. Cloth, \$5.00.

This compend of surgery is written on the basis of experience by one who has had the advantage of teaching students in medicine in the British Empire. Like the finished work of the English writers, this book is systematic, orderly in presentation, conservative in treatment and logical in outline. More a reference book than an exposition of surgical technic or procedure. The book has been rewritten every few years and this edition brings the advances in surgery up to date. This includes radium treatment and the surgery of the sympathetic system. A good book for every surgical library.

LUCENE W. SKELTON

A Short Encyclopaedia for Nurses.—By Evelyn C. Pearce. Octavo of 625 pages. New York, Oxford University Press, 1934. Cloth, \$3.75.

Not only is this unique encyclopaedia a panoramic scroll unrolled, but it completely details the essential facts about nursing care, and procedures made by heroes and heroines to bring world; but also it is compiled for a vast amount of reading and the material found in this book is scattered among many large heavy volumes. A wealth of knowledge is compiled in six hundred and twenty-five pages.

LAURETTE A. STOWE

THE FAMILY PHYSICIAN—PAST, PRESENT, FUTURE

ANDREW MACFARLANE M D

Albany

The training of physicians fifty years ago is a pathetic picture from our present scientific point of view but was effective in developing sturdy, reliant practitioners of medicine. The students needed no scholastic equipment except the 3 R's and could obtain medical degrees without even having attended clinics, lectures, or demonstrations. All they had to do was to sign up with preceptors, pay for two courses of lectures, each of four months' duration, and pass a cursory examination given by a medical faculty or committee in order to practice medicine.

Most of the medical schools were proprietary, contained no laboratories except the chemical, had no pathological or bacteriological departments, and except for a few clinics there was no attempt made to give bedside instruction to the students. Medical conditions were somewhat better in the great medical schools of New York, Boston, and Philadelphia, but even these were sadly lacking in practical training. It was at this time that the Johns Hopkins Medical School was organized due to the sad state of medical training in the United States and under the enthusiastic and brilliant leadership of Osler, Welsh, Halstead, and Kelly a new era started in medical training comparable with the best in Europe.

The one redeeming factor in this picture was the preceptor with whom the student had to register for his entire course. If he was a man of sterling character, keen observation, and of high ideals, like Dr McClure in the Bonnie Brier Bush, the student went to a real university and imbibed real medicine as he drove around in the doctor's buggy. In my day, registration in the office of Dr Albert Vander Veer was much sought after and almost

equivalent in value to the work done in the medical college.

The physician of that day had little or no comprehension of contagion or infection and based his medical knowledge largely upon personal experience, the value of which depended upon the keen observation and acumen of the observer. He carried a case filled with nauseous drugs in powder or liquid form, a few knives or other simple instruments very rarely a clinical thermometer (suggested by Allbut in 1867), and a stethoscope (developed in 1869).

The crude diagnosis of the patient or the family was often accepted. This relieved the physician from that responsibility and flattered the cleverness of the family. These hard-working pioneers ate very heartily of heavy foods, often not properly protected from decay and at times drank overmuch of strong liquors. The remedies of those days, emesis, catharsis, and bleeding, were indicated in many patients but carried to extremes or unwisely employed did much more harm than good.

Why therefore has there been a halo of romance developed about the old-fashioned doctor? He did not comprehend contagion, infection, nor diagnosis in the modern sense, but in times of trial and tribulation he was the trusted counsellor and the tried and true friend of the family. A shrewd observer with much common sense, he did his best and was both *nurse and physician* and gave freely of himself often without price. Then, too, when one keeps ever in mind that 80 to 90 per cent of the sick recover with or without, or even in spite of, treatment, he had very good sporting odds always in his favor for the gratitude of the patient.

A large part of medical work is not the

Read at a meeting of the Medical Society of the County of Albany April 25 1934

actual practice of medicine. It is, nevertheless, most valuable and consists in counselling, orienting, encouraging, and sympathizing, all with an understanding of the problems of the patient and his family.

There has always been a something about the practice of medicine which develops the best in man. A physician cannot witness the death struggle of a splendid and much needed head of a family, the excruciating pains of a mother in her desire to give birth to the longed for babe and the helpless struggles of the infant, the idol of the home, fighting vainly an incurable malady without making the physician a better, more considerate, and kindly man, although he cannot comprehend the meaning of these mysteries of life.

Fifty years ago, hospitals were medical almshouses (80 per cent were charity cases), and the sick entered them only as a last resort and left all hope behind—a fear too often justified. No attempt was made to classify patients or to isolate contagious cases, and there was no understanding or appreciation of infection in what was then supposed to be surgery. There was no apparatus or appliance for diagnosis or treatment. Few hospitals had even a modest, efficient clinical laboratory before the beginning of this century. The cost of hospital maintenance was about one-fourth of that at the present time, but the average duration of hospital residence was twice as long and the mortality very much higher.

The work of Pasteur, a French chemist, Lister, a British surgeon, and Koch, a German district physician, marked for mankind the beginning of the most glorious epoch in the history of the world. These convergent discoveries with many subsequent laboratory findings created and developed a scientific understanding of communicable diseases which led to an almost unbelievable evolution in the theory and practice of medicine.

The science of medicine then leaped far in advance of all other sciences not alone in actual technical knowledge but in the tremendous reduction in mortality and in human suffering with a coincident extension of life. It is no exaggeration to state that medicine has already repaid manyfold in the protection of life, the prevention of suffering, and even in the actual saving of money, all the wealth which has been so generously and lavishly bestowed upon it.

The practical blotting out of smallpox, typhoid, yellow fever, cholera, typhus, malaria, hookworm, diphtheria, scurvy, and rickets need only be mentioned. This is a record which is easily the outstanding achievement of our civilization, but it is so universally accepted as to have become a mere commonplace.

The marvels of modern surgery rendered possible by the discoveries of anesthesia and asepsis are well known. The use of technical instruments for x-ray, electrocardiograms, metabolic reactions together with diagnostic tests as Wassermann and those of blood chemistry make modern medicine a veritable wonderland of almost romantic knowledge.

To-day the physician has to take a two-to four-year college preparatory course, thirty-six months in medical school, clinics and laboratories, and eighteen months post-graduate residence in hospitals. He must also pass a rigid state examination in order to practice medicine. All this at a minimum cost of \$16,000 and at least seven to nine years of time easily three times in expense and years what it was.

He carries a bag about the same size as that of his predecessor. It contains a small case of emergency remedies carefully standardized together with a hypodermic syringe, sterile dressings, and instruments. In addition to his clinical thermometer and improved stethoscope it holds a blood pressure apparatus, blood-counting instruments, sterile swabs for diphtheria, tubes for typhoid determination, Wasserman tubes, sterile bottles for sputum in the diagnosis of tuberculosis and of the type of pneumonia, bottles with syringe for blood chemistry determination and glass slides for pathogenic organisms. What is the difference between the physician of the past and of the present? The former had not been given much scientific knowledge but he was a keen observer (Dr. Joseph Bell of Edinburgh—the prototype of Sherlock Holmes), sturdy and self-reliant, the frontier type, a tough guy. He had many difficult problems, but he had to solve them, alone and without aid. He had to give more personal service. As he drove away in his gig from his dying patient, he pondered and thought for hours on the reason for the unanticipated change in the symptoms and what more might have been done for his patient. What more illuminating descriptions of disease than those of Addison, Trousseau,

Niemeyer, and Flint. He was a personal doer both as a physician and a nurse. The modern graduate knows so much more theoretically that he keenly realizes how little of that knowledge is created by himself. He becomes the victim of a huge diagnostic machinery. He awaits reports and unconsciously conveys to the patient his uncertainties in diagnosis. Then it is too often forgotten that the real training of the physician comes after his entrance into practice.

The development of modern medicine has been characterized by certain outstanding manifestations.

(1) The enormous growth of the science of medicine involving many tests necessitating expensive apparatus, great technical skill and experience, and much time.

(2) The tremendous increase in the number of specialists.

(3) The lamentable decrease in the relative number and remuneration of the old-time family physician who has always been the counsellor and friend of the family and the wheel horse in bearing medical aid and comfort to the stricken family, night and day.

The family physician relied upon his knowledge of the patients personal and family history together with his power of observation and long experience with disease processes. Personal physical examination was his sheet anchor, and upon his accuracy and acumen depended his success. To-day the physician relies for his diagnosis not only upon history and physical examination but especially on various laboratory tests which are more exact than the results of physical examinations. The physician is thus often tempted to depend too much upon these extraneous aids, short cuts, and too little upon his own skill and mentality.

The extension of medical knowledge into the recesses of the body and the use of recently discovered local anesthetics has enabled many manipulations and minor operations to be done in the office of the physician-specialist. A goodly fee is gladly paid for such services which, though rarely serious, give great comfort and relief to the patient.

The general practitioner's income has been markedly reduced by the disappearance or decrease of such diseases as typhoid, by the modern treatment of tuberculosis, malaria, diphtheria, rickets,

etc., which formerly produced a considerable part of his fees.

The worthwhile activities of industrial medicine and the splendid work of the state in preventive medicine among school children, in the development of medical clinics for adults, by the oversight of water, milk, and food supplies are responsible for still further reduction in income. The specialists who have invaded every field of medicine and assumed the attitude of super-medical skill, have attracted especially his most lucrative type of patients.

The general practitioner is no longer the central figure in the healing art. He has been squeezed into a helpless and almost hopeless condition between the upper and nether millstones. He now has an average income of \$2,500 per year, about one-third of that of the specialist, yet he is expected to know and do everything. He has allowed himself to be beaten, cowed, and pushed aside. The public has begun to doubt his capacity and usefulness. He shows evidence of an inferiority complex. The motor car has made it easy for his well-to-do patients to consult more or less continually the prominent physicians in nearby centers of population. They call upon him only for emergencies. Everyone realizes how the strain and stress of an indecently low income too often undermines the morale for service and destroys the stimulation to study and progress. An other instance of "progress and poverty," progress in science; poverty in income.

The teachings of medical schools have so stressed the importance and significance of all technical methods of diagnosis that the recent graduate in medicine fears that he cannot efficiently and successfully practice medicine without all these extraneous aids. He does not appreciate that Janeway, Loomis, Delafield, Osler, Alibut, and many other giants in medicine did excellent medical work by the use of their gray matter and five senses and a broad clinical experience.

He is often afraid to attempt practice in the rural districts because he will be away from the aid of hospitals and laboratories. This lack of self-confidence together with the hard work, poor compensation, inferior schools for his children and few social contacts for his family persuade him to crowd into cities already oversupplied with physicians. The rural sections have become medically neglected and often have to

pay a substantial bonus to secure the services of a young well-trained physician to settle in their community.

Complaints have recently arisen about the present high cost of medical services, and magazines contain articles deploring the latterday commercialism of medical practice. "The High Cost of Babies," "A Cure for Doctor's Bills," "Mr. Brown Pays His Hospital Bill," are typical. These complaints are indeed few in the vast medical service rendered throughout this country and it is surprising that such complaints are not more common.

The reports of the Committee on the Costs of Medical Care have not solved this problem because to a very large extent they have failed to recognize the human elements which play such an important part in the practice of medicine.

The crux of this medical problem is the present and future status of the family physician, the first line of attack—the shock troop. He must be restored to his full rights if progress is to be continued to be made toward the adequate care of the sick and if our entire present medical service is not to be destroyed.

Medical practice to-day can be compared to a modern skyscraper. The foundation and first few floors are the family physicians, then the twenty-five stories above are the specialists — surgery, ophthalmology, laryngology, neurology, obstetrics, gynecology, etcetera ad infinitum. If such a structure has weak or insecure foundations or becomes topheavy, it falls. Every student of medical practice and tendencies recognizes these facts, and all bewail the present plight of the family physician, but no one even offers a remedy. It reminds one of Mark Twain's bon mot about the weather: "Everyone complains of the weather, but no one does anything about it."

The family physician's income is growing rapidly less and less due to competition of the specialist, the disappearance of certain diseases which formerly made up a considerable part of his income, by increasing industrial medicine and by the preventive work of full-time health officers. The only remedy for this condition is more remunerative medical work for the family physician or he will pass off the scene in spite of the many expressed regrets.

All indications point to the fact that from this time on the population of the United States will not continue to increase

to any measurable degree due to the fall in immigration and to birth control whether legalized or not. This country with practically stationary population will occupy the same position as does France to-day. The medical schools, however, are graduating each year 2,000 more physicians than are retired. This means 10,000 more physicians in five years than are needed; 20,000 more in ten years; while the field of medicine each year becomes more and more restricted. This, however, is the problem of the medical schools. They must remedy this condition of overproduction before the medical profession is completely submerged in its struggle for existence. Physicians cannot be burned up like wheat, cotton, hogs, etc.

The slogan, "Adequate Medical Care for Everyone," is naturally appealing, but equally effective would be such slogans as "Nutritious Foods for Everyone," "Comfortable Shelters for Everyone," "Warm Clothing for Everyone." Does anyone expect that the butchers and bakers, builders and tailors will rush to provide these necessities without compensation? Much more important for the health of a community are the cleaning up of the slums, nourishing foods, sanitary dwellings, and warm clothing than all the drugs in the pharmacopoeia. Why load upon the medical profession alone the eradication of this canker sore of civilization? The public too often has looked upon the illness of the slums and the submerged tenth as a cause and not a result of conditions for which everyone is responsible and the physician not more than his neighbor.

The family physician must be saved. Upon his salvation depends the future of the medical profession. This can be accomplished by improving his position in the community and providing him with more interesting and more remunerative work. This can be accomplished by:

(1) The employment of general practitioners in all direct diagnostic public health contacts with the public—The Detroit Plan. Every physician would assume his true position and be directly responsible for the health of the community which in turn would look to him for guidance in all matters of health. He would naturally be the first to see every communicable disease and would be keen as an associate health officer to recognize and report it in its incipency. This has

been strikingly shown by the fact that deaths from tuberculosis since 1900 have been reduced four-fifths largely because physicians have become keen on the diagnosis of early tuberculosis. This development would immeasurably help preventive medicine and restore the true status of the physician in the community as the one who diagnoses, treats, and prevents disease.

(2) The general physician should be furnished at a community institute at little or no expense every diagnostic laboratory and needed in doubtful cases. Such knowledge would often enable the physician to make a correct diagnosis early and would at times save life and often prevent physical suffering and mental torture.

Diagnosis is not a God-given gift but depends upon the intelligent interpretation of the significance of the largest number of facts obtainable. The specialist, outside of technical details and an intensive but limited experience, is not naturally superior to the competent general practitioner in diagnostic ability, but he demands in an obscure case all the facts before he is willing to arrive at a diagnosis. The patient, when he consults the specialist has become so alarmed about his condition that he is now only too willing to undergo any number of tests. If some of these tests reveal the correct diagnosis, the specialist is glorified and the family physician falls in the estimation of his patient. If nothing is found, the patient is now mentally relieved and again glorifies the consultant and damns the general practitioner for not finding out the truth earlier. The cost of such examination to a family in moderate circumstances is a matter of much moment to the family physician but if the expense was made little or nothing, he would not hesitate in a doubtful case which did not promptly get well. The result would be that the family physician would necessarily become more scientific in his outlook upon disease. He would practically be the equal of the specialist and his standing in the community correspondingly elevated.

The community could easily enlarge its present laboratory's facilities so that blood tests, x-ray reports, electrocardiograms, metabolic studies, gastro-intestinal examinations and tests for allergy, hay-fever, skin and deficiency diseases, and arthritic conditions could be made at little or no cost to the patients. The request of the family physician with a history of the case would be sufficient reason for such ex-

amination. This would lead to the early discovery of conditions before they became overwhelming and thus develop personal preventive medicine.

The costs to the community would not be prohibitive. In fact such a diagnostic laboratory might easily be made self-supporting. Regardless of the expense why has not the man of small income—the back-bone of the nation, the right for himself and family to every aid which will hasten his recovery? Must such help be restricted to the rich and to the poor? The great middle class which has always borne the burden has never been fairly treated. One of the greatest evils of medical practice is the frequent treatment of disease without a diagnosis to the fullest extent now available.

MacKenzie emphasized the possibilities of the family physician recognizing obscure symptoms in their early stages and to follow them through their life development and even from generation to generation. This privilege would immeasurably stimulate such observations and lead to incomparable results. The real joy of medicine depends on mastering its mysteries.

The present state medical law is now about fifty years old, and during this time almost unbelievable changes have taken place. The specialties and especially surgery, to day so often involve life and death that no one unless thoroughly competent should be allowed by the state to put the life of anyone in unnecessary jeopardy.

The state should not permit any physician to call himself a specialist except after a special, practical examination and three to five years training in that subject and preferably only after several years of independent work in general medicine in addition to this special training. The state might consider the wisdom of reexamining once or oftener all physicians actively engaged in the specialties and as a result of such tests continue to permit or rescind this right.

The American College of Surgeons has attempted to decrease incompetent surgery by determining the competency of surgeons to become members of their organization. This effort has had little influence on the layman who often has no way to determine the training and experience of the operating surgeon.

The family physician must recognize the fact that he should make use of the modern advances in medicine if he is to continue to

fulfill his part to his patients and not be simply a medical traffic officer in time of danger. He can continue to practice independently as at present, seeking such aid as he may deem necessary from laboratories and consultants.

A modern tendency, however, with much in its favor, is for physicians and dentists to form medical groups in a building designed especially for their needs. The groups are often financially cooperative, but there is always the possibility that some one in the group will become the dominating personality in the organization and the other members subservient and thus lose their individual personalities and freedom. Each physician, however, could preserve his professional independence and simply share in a medical office building, dividing pro-rata the expenses of the office, secretary, and laboratory technician.

There are decided advantages in the private group system for the physician; the professional stimulation arising from a close contact with congenial and progressive physicians in kindred lines of work; the ease of obtaining at once laboratory aids when indicated, the possibility of immediate consultations probably at reduced charges for the patient by the associated office consultants as all the data would be completely presented.

The group system furnishes at a low cost to the individual physician, expert technical and clerical assistants thus taking off the doctor's shoulders the necessary but annoying and too often neglected minutiae of his work, as the keeping of records, correspondence, posting of charges, and making out of statements.

The growth of medical science has been so marked and marvelous that the medical schools have emphasized too much the science of medicine and have placed too little stress upon the art of medicine. The result has been that the practitioner has neglected the small things of medical practice which add much to the comfort of the patients and make up a large part of medical service. There has been developed as a protest, apparently successful cults which depend practically entirely for their success upon massage. In spite of their inferior knowledge of the fundamentals of medical science and the mistakes they must at times necessarily make, they seem to give relief and comfort to many intelligent patients by their manipulations and thus gain much support. The great increase in cults with the accepted tremendous devel-

opment in medical science is a contradiction not seen in any other field of human endeavor and must have a reason.

If the medical student in his senior year and hospital internship would receive thorough and practical courses in massage, hydrotherapy, electricity, light, and heat treatments which he could employ in his practice, much could be done to eliminate these cults, to increase his income, and to strengthen the practical and financial standing of the general practitioner in his community.

The determination of a serious condition at the earliest possible moment may test to the utmost the diagnostic skill of the best physician and also be responsible for some of the increased costs of medical service. A man between fifty and sixty years of age, valuable to his family and community and who has been very well, consults his physician about such a simple and common condition as headache from which he has recently begun to suffer. Headache may be the complaining symptom in at least seventy-five different pathological conditions ranging from constipation, eyestrain, and anemia to cerebral syphilis, brain tumors, and drug poisons. The correct diagnosis, at times necessitating a number of examinations by specialists and of laboratory tests, may prove to be simple and easily remedied, or a serious condition which may require expert care or an immediate operation. These careful and critical examinations are expensive in time and money and the patient often but unwisely may feel aggrieved when nothing organic has been found after so great an expense. If the physician attempts to save the expense involved, with the hope that the condition is simple and self-limited, he may learn too late that he has grievously failed both for his patient and for his own reputation.

This complete examination is being attempted at a number of hospital clinics in the large cities at a moderate cost. This work has, however, antagonized many family physicians as their patients often go independently to the clinics and then later employ other physicians especially if the family physician has overlooked conditions found at the clinic. It would seem best for all concerned that the clinics insist that patients be referred to them from their family physicians or at least ascertain from the patients the name of a physician to whom their findings and records must go. The clinic should at all times impress

upon their patients the value of their family or neighborhood physician.

The complaint of the high cost of medical service is almost always a purely local question and limited except in very exceptional cases to the large centers of population. No one has ever heard complaints about high medical costs in the rural districts or in the smaller cities or by the family physicians. It is a problem restricted to our very largest cities and involves only the charges of the specialists in these communities.

What is the reason for the high cost of medical services by specialists in the metropolitan centers? A physician becomes justly renowned and many patients flock to him for relief. He must necessarily limit the number of patients whom he is physically able to examine and treat. There is only one way in which he can limit the number of his patients and that by his professional charges. Much of his time is spent in teaching, in hospital ward attendance and in research work for all of which he receives no direct compensation, simply the added professional prestige arising from these associations.

No one begrudges the large fees obtained by one, who as a result of hard work and great ability has become a leader in his profession. He necessarily establishes a high standard of charges but unfortunately other physicians doing the same kind of work with unequal skill and ability feel in justice to their assumed reputation, their fees should be correspondingly high.

The public, too, is largely responsible. They do not seem to realize that in large communities there are many equally careful obstetricians, efficient surgeons and meritorious specialists. The apparent desire of the *homo americanus* especially the one of the female species is usually to have the most expensive in everything as indicative of the best.

Unfortunately, it is difficult for the layman to know accurately the real ability of a physician. Too often the selection is dependent upon chance, a casual recommendation, or whether he is the fashion and the interesting subject of gossip at bridge, luncheon, and dinner tables. It takes a brave woman to announce to her friends that she is going to have a socially unknown accoucher for her confinement or a young surgeon for her operation.

Efficient medical service must not cost more than the recipient can pay. This is impossible of accomplishment under present conditions in obscure and difficult cases in the working class. Each community, however, could easily extend the activities of its present laboratory so that every aid to diagnosis could be given to the physician at little or no cost.

Physicians should receive a just return for their investment in their profession and for their professional work. This could be accomplished by extending the work of the family physician. He should be trained to do much of the work done at present by the specialist and practically all the clinical work of the department of health.

Physicians who achieve unusual skill should be able to earn incomes comparable with those of the leading lawyers and business executives in the same community.

Physicians should not be expected to carry the burden of medical charity work, a communal problem, and are entitled to modest compensation for this work.

The challenge of the future—public health and adequate care of the sick—is only in small part a medical question. It involves and tests the adequacy and efficiency of modern civilization with its poverty, vice, ignorance, bad housing, poor food, and insufficient clothing for the submerged tenth in our country and especially in our cities. If these conditions are remedied, the adequate care of the sick would become a simple problem easily soluble.

The attempt to load all the responsibility for the correction of these evils upon the medical profession is fatuous and will never lead to a true appreciation of the depth and difficulty of this question or to a corrective solution of a problem which is the problem of all and not of a class.

The medical profession has already done a marvelous amount of philanthropic work with little recompense and less credit. It will always be a valuable collaborator, but never will it be able single-handed to clean out this Augean stable of vice, intemperance, and ignorance—the blight of our civilization.

Continued progress in public health arising from a clearer understanding of disease processes and from the resulting advances in preventive medicine is the ultimate goal of all medical activities. This must inevitably lead to a constantly increasing part

played by public health physicians in the medical activities of our complicated civilization. The exact character of these changes cannot now be foreseen, but it takes no prophet to predict that the American people will demand and eventually receive the best possible medical service.

In conclusion let me present for your serious consideration the following thoughts.

(1) The state should permit legalized practitioners of medicine to qualify as specialists only after 3 to 5 years of special training, the value of which should be determined by a practical state examination.

(2) The community should recognize the value of the family physician by employing his services as far as possible in preventive medicine and in providing him

with all possible, practical diagnostic aids.

(3) The medical schools should reduce their student bodies about one-tenth in number. They must recognize that their first duty is to educate efficient physicians and to so train them for family practice that they may render valuable and creditable service to the community.

(4) The general practitioner must justify by his character and type of practice all the glorious heritage of medicine and the splendid aid given him by community and medical school.

He must realize that he is not alone a rugged self-reliant individualist, but that to accomplish his best work in our complicated civilization he must do team work and cooperate with his brother practitioners in his manifold activities.

ANNOUNCEMENT

The State Department of Health has for several years issued a circular in pamphlet form entitled, "Information for Physicians" regarding the State Department of Health, the Public Health Law, and the Sanitary Code as it applies to the State outside of New York City. The 1933 edition is now running out and, before undertaking revision and reprinting, the Department is eager to know whether any considerable number of physicians use it and believe it helpful. The pamphlet carries advice about phy-

sicians' duties in communicable diseases and advice as to procedure of quarantine, etc.

There is also a "Laboratory Manual" containing full information of the services the Division of Laboratories and Research is prepared to render to those who ask for it in connection with which the Department would like similar information. It is, therefore, asked by the Department of Health that the physicians throughout the State, outside of New York City, communicate opinions to the Department by mail.

1934 GRADUATE FORTNIGHT of the NEW YORK ACADEMY OF MEDICINE

The Seventh Annual Graduate Fortnight of The New York Academy of Medicine will be devoted to a consideration of gastro-intestinal diseases. The Fortnight will be held October 22 to November 2.

Sixteen important hospitals of the city will present coordinated afternoon clinics and clinical demonstrations. At the evening meetings prominent clinicians from various parts of the country who are recognized authorities in their special lines of work will discuss the various aspects of the general subject.

A comprehensive exhibit of anatomical, bacteriological, and pathological specimens and research material will be shown. Many of the exhibits will be demonstrated.

Among the subjects to be presented at the evening meetings and in the hospital programs will be:

General principles involved in the diagnosis of gastro-intestinal diseases—medical, surgical, roentgenological

Constipation
Diarrhea
Physiology of the gastro-intestinal tract
Diseases of the pancreas, especially acute pancreatitis and its treatment
Diseases of the esophagus

Functional diseases of the stomach
Disorders of the gastro-intestinal tract in children—
infections, management, surgery in infants and children
Diet in relation to gastro-intestinal diseases in infancy
Clinical examination of the patient from the surgeons
and the internists' points of view.

Demonstrations of diets used in treatment
Peptic ulcer—medical discussion, surgical discussion
Carcinoma of the stomach
Chronic lesions in the paracecal region
Acute appendicitis
Peritonitis
Gallbladder and biliary passages—medical discussion,
surgical discussion

Jaundice
Tumors of the colon
Diseases of the rectum, including tumors
Intestinal obstruction
Diverticulitis
Colitis, amebiasis, functional disturbances of the colon
including mucous colitis
Hirschsprung's disease
Lymphogranulomata
Clinical methods and differential diagnosis
Technic of the gastro-intestinal series
Laboratory examinations.

The profession generally is invited to attend.
A complete program and registration blank
may be secured by addressing:

DR. FREDERICK P. REYNOLDS,
The New York Academy of Medicine,
2 East 103d Street, New York City.

PRACTICAL CONSIDERATIONS IN THE DIAGNOSIS AND TREATMENT OF POLIOMYELITIS

IRVING J SANDS M D

Brooklyn

It is of paramount importance for the clinician to recognize poliomyelitis and institute treatment as speedily as possible. A practical consideration of these phases of the subject, therefore, seems opportune.

Anatomically, acute poliomyelitis is a meningo-encephalomyeloradiculitis.¹ Despite the fact that signs and symptoms are referable to the involvement of only certain portions of the central nervous system, pathological studies of the acute cases reveal a diffuse involvement of the nervous system, with inflammatory changes occurring in practically every part of the central nervous system. Nevertheless, it is a fact that the anterior horn cells of the spinal cord, and particularly those of the cervical and lumbar enlargement, and the nuclei of some of the cranial nerves, especially those of the 7th, 9th, 10th, and 11th, and, in a lesser number of instances, of the 6th, and 12th cranial nerves, bear the brunt of the lesion. At least, the vast majority of cases show this to be clinically true, and the ensuing paralyses are the result of the involvement of these nerve groups. At necropsy one is impressed with the marked edema and congestion of the entire nervous system. The brain generally weighs 10 to 15 per cent in excess of its expected weight. The ventricular system is compressed by the edematous brain tissue. There is marked congestion of the pia, especially at the base and particularly at the pons and medulla. The spinal cord is edematous and congested, and its vessels, especially on the anterior surface, are swollen and tortuous. Sections of the cord and medulla will disclose marked hyperemia of the gray matter and particularly of the anterior horns, which stand out prominently from the rest of the tissue. Microscopically, there are striking mesodermic and ectodermic changes. The pia is edematous and thickened, and its vessels are engorged. There is proliferation of the fibrous tissue, and there is infiltration of lymphocytes, polymorphonuclear cells, and red blood cells. The pia vessels show striking inflammatory changes with infiltration of the Virchow-Robin spaces with lymphocytes, polymorphonuclear cells and plasma cells. Hemorrhagic areas are not

as frequent as one might gather from the literature, yet occasionally they are encountered, especially in the anterior horns. The ectodermic tissue shows changes both in the neurocytes and the glial tissue. The motor cells show cloudy swelling, chromatolysis, satellitosis and neuronophagia. The most extensive pathological alterations are found in the motor cells of the anterior horns and in the ganglia of the cranial nerves that are involved in this disorder. One occasionally encounters areas in the anterior horns that are devoid of neurocytes, the latter having been replaced by lymphocytes, polymorphonuclears, and glial cells. The microglia is particularly active in the acute phase. The characteristic infiltration of the Virchow-Robin lymph spaces is particularly evidenced in this disorder.

As previously pointed out despite the diffuse anatomical lesions encountered in the nervous system clinically, the patients present themselves in the following groups:

(1) The meningeal type, in which the predominant picture is one of meningeal irritation.

(2) The bulbar type, in which the involvement of the cranial nerves is the most significant clinical picture.

(3) The myelitic type, in which pareses and paralyses of the skeletal and limb muscles and of the diaphragm are encountered.

(4) The bulbomyelitic type, which is characterized by clinical signs referable to the lesions of the cranial nerves and the peripheral motor nerves.

(5) The encephalitic type, which is usually associated with signs referable to bulbospinal involvement and characterized by extreme drowsiness, stupor, aphasia, pupillary disorders, sphincteric disturbances, and even convulsion.

To these types may be added

(1) The spreading or Landry's, type, which is characterized by either ascending or descending paralysis involving progressively different groups of muscles, and

(2) The abortive types,² which expresses itself clinically in an acute, mild, febrile disorder, with headache, vomiting, malaise,

and general gastro-intestinal symptoms, and which is hardly recognized except during epidemics of poliomyelitis.

The diagnosis is made upon the history of the onset of the illness, the physical examination, and the spinal fluid analysis. The onset of the illness may be characterized as "cerebral" in nature—headache, vomiting, and constipation, associated with restlessness, irritability, insomnia, or more commonly somnolence. On examination the patient appears somewhat apprehensive and anxious and resents the examination. The face is flushed and the patient appears prostrated. The signs of meningeal irritation are pronounced, there being rigidity of the neck and a mild Kernig sign. One must employ considerable tact and skill in eliciting the nuchal rigidity and the tenderness and rigidity of the spinal muscles, particularly in dealing with children. Many devices must be employed in order to bring out rigidity of the spinal muscles. Various signs have been described which collectively come under the general heading of "spine tests." The object of these tests is to elicit the pronounced spasm in the muscles of the neck and of the back. One of the most valuable signs to which my attention was directed by Dr. Emil Smith, resident at the Kingston Avenue Hospital, is the tache. By gently, though firmly, passing the tip of the palmar surface of the index finger, or the angular end of the rubber hammer, across the skin, one elicits a characteristic tache. There ensues a red-brown discoloration on the skin about 1 or 2 cm. in width, which lasts for approximately 1 to 2 minutes. Occasionally this test has proven of value in predicting the group of muscles to be paralyzed, as it seems to be of a segmental character. In those cases which subsequently develop cranial nerve signs, the tache was elicited over the lateral aspect of the neck on the side where the cranial nerves were involved. This test has served the author well in several instances and is not receiving the attention which it merits. The temperature is generally about 101° to 103° F., usually about 102°. The pulse is around 120. The blood count shows between 10,000 and 15,000 WBC, with a polymorphonuclear cell count of 45 to 60 per cent, there being a relative and absolute lymphocytosis. The temperature may continue for 3 to 5 days, and then subside, the patient getting well, having recovered apparently from the meningeal type of poliomyelitis.

In the myelitic type there ensues in a day or two after the onset of the illness weakness or paralysis of a group of muscles of the limbs, abdomen, thorax, or diaphragm. In the bulbar type there is involvement of the cranial nerves, the 7th, 9th, 10th, and 11th being the ones principally involved. Nystagmus is commonly present. Drs. Smith and Fineberg,³ of the Kingston Avenue Hospital, have recently presented a practical and illuminating article on bulbar poliomyelitis and its treatment as used in the Kingston Avenue Hospital during the epidemics of 1931-1932. They describe bulbar poliomyelitis under the following headings: (1) Those in which there is unilateral paralysis of the palate, with congestion of the pharyngeal wall fauces and mucous membranes, lagging of one side of the palate, and a slightly nasal tinge to the voice, difficulty in swallowing for a day or two, and weakness in coughing, with occasional involvement of one-half of the tongue. The temperature generally subsides in this group in 5 to 10 days, and recovery usually ensues. (2) Bilateral paralysis of the palate with increasing nausea and salivation, uniform congestion of the oral cavity, collection of mucus behind the posterior pillars, inability to expectorate the mucus, labored respirations without supra- or infrasternal restriction, nasal voice, indistinct articulation, marked difficulty in swallowing, especially of liquids, and regurgitation through the nose, and with a very slow recovery and persistence of signs for many weeks. These observers noted that no extension of paralysis had occurred after the temperature had remained normal for 48 hours. In this group of cases they pointed out that involvement of the vasomotor center is invariably fatal. In the bulbo-myelitic type there is a combination of the signs and symptoms encountered in the bulbar and myelitic type.

The spinal fluid is under moderately increased pressure, usually between 120 and 200 mm. of water. The cytology may be from 20 to 1000, or more. Usually in the myelitic type one encounters from 50 to 200 cells; in the bulbar type between 50 and 75 cells, and in the meningeal type from 100 to 300 cells. There is considerable controversy as to the type of cells encountered on the first day of the illness.⁴ The author's experience has been that the polymorphonuclear cells predominate if the spinal fluid is examined immediately after withdrawal. After the second day of the

illness, the lymphocytes predominate. The sugar and chloride contents are normal. The colloidal gold curve is of the very mild parenchymatous type. There is a slight increase in globulin.

There is considerable difference of opinion amongst competent physicians as to where, when, and how poliomyelitic patients shall be treated. There is a group whose philosophy is that of therapeutic nihilism,⁵ and their principle is to leave the patient alone, making him as comfortable as possible, maintaining that the average case will get well without any active therapy. On the other hand, many in the field believe that there should be an active and early institution of therapy in this disorder. Moreover, poliomyelitis causes such a marked emotional disturbance, not only in laymen but also in the profession that several communities will refuse to have a poliomyelitic patient admitted to a general hospital. Last summer patients were refused admission even to the private pavilion of a well known general hospital because many physicians threatened to withdraw their patients from the hospital if poliomyelitic patients were admitted there. Such an attitude is both unscientific and inhuman, and is based upon sheer lack of understanding of the entire problem. As a matter of fact poliomyelitis is not contagious in the ordinary sense of the word and moreover the entire problem of carriers and its method of infection is still a mooted one. One fact is certain—that infection amongst physicians and nurses treating poliomyelitic patients, or in patients lying alongside poliomyelitic cases is indeed a medical curiosity. It is my opinion that patients with poliomyelitis should be treated in a general hospital. This would tend in a measure to allay the panicky state of mind that occurs during an epidemic. It would relieve the congested wards of the hospitals for contagious diseases to which these patients are sent, and would afford considerable opportunity for study of this problem by a larger group of physicians and might eventually lead to discoveries of methods of treatment yet unknown. It would prove of benefit to the patient, to the physicians and to the lay public.

Serum therapy has been the chief source of difference amongst physicians. It is a known fact that a vast majority of patients recovering from poliomyelitis contain in their blood an immunizing substance which

neutralizes the poliomyelitic virus. Moreover, it has been found that this substance is present in the blood of most adults who may not have had poliomyelitis.⁶ Animal experimentation⁷ has proven the value of this serum. There is an increasing number of published reports on the value of immune serum in the treatment of poliomyelitis.⁸ All, however, agree that it is most effective when administered before the onset of paralysis. Furthermore, the earlier the serum is administered the better the results. Some agree that there is great value in serum therapy even after some parestheses or paralyzes have occurred.⁹ The author's experience has proven to him the value of immune serum when administered early in the disease and in the proper manner. Serum should be administered intravenously or intramuscularly, and never intraspinally. The latter method cannot possibly reach the virus and causes marked aseptic meningitis,¹ which adds to the edema and therefore, to the compression of the delicate cord tissue. On the other hand, when given intravenously or intramuscularly, it is bound to reach the virus and neutralize it to some extent. The writer has used blood transfusion¹ in the first 24 hours of the disorder with remarkable benefit, employing a recovered poliomyelitic patient as a donor. Such donors, however, are not always available. Therefore, ordinary donors¹⁰ may be used on the principle that their blood contains immunizing substances, as proven in most adults. Pooled serum from poliomyelitic patients could be used effectively, both intravenously and intramuscularly, 50 cc being given in the vein and 25 cc in the buttock. This may be repeated within 24 hours. Only too often one meets with the argument that once the nerve cell is destroyed, nothing could help it. While this is true no one can tell when and where the paralyzes will stop, and many patients with the spreading, or Landry's, type of paralysis may be saved if serum is administered even after the initial onset of paralysis. As pointed out by competent observers,¹¹ watching these patients one by one is more convincing than any statistical report could possibly show the value of serum therapy.

Spinal puncture is not done as frequently as formerly, for its value in reducing edema is not very great, and in bulbar poliomyelitis sudden release of spinal fluid may cause changes in the pressure within

the fine capillaries of the medulla, resulting in their rupture and increasing the pathological changes in the medulla; it may be indirectly responsible for the death of the patient.

The edema that is present in the nervous system in this disorder requires skillful management, for it contributes materially to the injury of the nerve cells. Hypertonic solutions of glucose intravenously, 250 c.c. of a 25 per cent solution, will reduce the edema and furnish considerable nourishment to the patient. It is particularly helpful in bulbar poliomyelitis.

Forced spinal fluid drainage, as introduced by Kubie,¹² is based upon experimental, clinical and pathological observations and is a real contribution to the treatment of infections of the nervous system. While the author had no personal experience with this method in poliomyelitis, it certainly should prove of value after the onset of paralyses, and particularly in the encephalitic forms of poliomyelitis.

The bulbar type of poliomyelitis requires special skill in its management. The patient should be put in the prone position upon a hard mattress and the foot of the bed elevated to insure drainage. The accumulation of mucus in the back of the throat should be removed by swabbing, or preferably by suction. It is imperative that these patients receive fluids either by rectum or by hypodermoclysis. Hypertonic glucose, intravenously, serves the double purpose of furnishing nourishment and fluids, as well as reducing edema. According to Smith and Fineberg, nasal gavage should not be begun until the temperature has subsided, and then only in small amounts, to obviate vomiting.

The respirator¹³ should be used for patients who show diaphragmatic or intercostal muscle paralysis. It should not be used when respiratory embarrassment is caused by involvement of the medulla.

When one considers the seriousness of poliomyelitis, intramuscular administration of immune serum or parental blood to children is both a sensible and practical prophylactic measure. It would seem reasonable to expect public health authorities to be prepared for future epidemics. This would necessitate the obtaining of sufficient amount of serum from patients who have recovered from poliomyelitis. Moreover, it would be advisable to test the ordinary certified donor's blood for antiviral properties. He should then be properly

certified so that when required he could be called upon to give blood to the poliomyelitic patient. Considering the fact that billions are justly spent for industrial recovery, the sum of money spent on properly securing immune sera and certifying immune donors would indeed be insignificant and trivial, and would save many a life and limb.

SUMMARY

(1) The onset of poliomyelitis is characterized by headache, vomiting, and mild temperature. The signs are primarily those of meningeal irritation. The value of the tache as a diagnostic sign is emphasized. The various clinical types of poliomyelitis are described.

(2) The administration of serum early in the disease is emphasized.

(3) The advantages of treating these patients in a general hospital are discussed.

(4) The duty of public health authorities to organize for effectively combating epidemics by accumulating immune serum and certifying donors whose blood contain antiviral bodies is discussed.

THE TREATMENT OF ERYTHROBLASTOSIS OF THE NEWBORN

DOUGLAS P. ARNOID, M.D. and RICHARD A. DOWNEY, M.D.
Buffalo

We are not greatly concerned whether erythroblastosis is the correct term in designating the associated hemolytic conditions in the newborn which have been nicely correlated and described by Diamond, Blackfan, and Baty.¹ We are, however, vitally and practically interested in the proper and effective treatment of these cases, about which much has been written which is not only misleading but distinctly incorrect.

Concerning the *etiology* and *pathogenesis* of this group which includes universal edema, icterus gravis, and anemia of the newborn, there has been much discussion and interesting speculation,^{1, 2, 3} but until more is definitely known about such primary normal factors governing hemopoiesis, hemolysis, bilirubin formation, and metabolism, it seems idle to theorize concerning the more complex states which constitute the underlying factors in these hyperplastic hemolytic anemias of the newborn (we prefer this term).

We recognize edema of the newborn as the most severe and hopeless of these conditions. In fact, these cases are either dead at birth or succumb shortly after, and, at the present time, there is no effective treatment.

At the other end of the line, speaking from a prognostic viewpoint stands anemia of the newborn. This condition is a very definite entity, a member of this group, and must not be confused with any other anemia in infancy, nutritional or otherwise. Anemia of the newborn can be successfully treated by transfusion and, if necessary, repeated transfusions, plus proper general hygiene and diet. Of late, there are of this condition numerous descriptions.^{1, 2} The therapeutic indications, as will be described, are definite and if properly carried out will be rewarded with success.

Icterus gravis is the third member of this group. We see no reason why this term should not be retained. It is descriptive, for it is certainly an icterus and the condition is admittedly grave. Icterus gravis is the member of this group which demands early and specific treatment if effective results are to be expected.

These hyperplastic hemolytic conditions

in the newborn seem to be an abnormal continuation of the fetal medullary and extramedullary hemopoiesis coupled with an abnormal accentuation and prolongation of the physiologic process of hemolysis in the newborn.^{4, 5, 6}

The *diagnosis* depends on a rapidly progressive jaundice and anemia, usually with apathy but sometimes with twitching and convulsions. The hemoglobin and number of red blood corpuscles drop rapidly, the bleeding time is prolonged, fragility tests are not constant, hemorrhages may occur, the spleen and liver are enlarged, and there is usually but not always an erythroblastosis and reticulocytosis accompanied by the appearance of immature leukocytes in the peripheral blood.

The *minute findings* and *postmortem* diagnosis will not be described, this has been admirably done many times.

If early treatment is essential—and we feel this is of prime importance—the differential diagnosis must separate this pathologic hemolysis from ordinary or marked cases of physiologic icterus. We all have had cases of physiologic icterus which have been deeply jaundiced and have also shown some drowsiness. These have caused us some apprehension but have cleared up without specific treatment. When then, are we dealing with a marked physiologic icterus and when does this hemolytic process become severe enough to be considered pathologic, consequently severe enough to be dangerous and require specific treatment?

The picture of icterus gravis is not always complete with all the signs and symptoms mentioned in chronological order. In fact, we are faced here with another medical condition which requires judgment. Medical or surgical judgment is always based on facts properly correlated with resulting logical conclusions. In this particular instance the typical picture may be more or less complete. Clinically, however, the factor which must be carefully watched is the hemoglobin and, because of the rapidity of the hemolysis in some cases, the hemoglobin must be taken and recorded several times a day as is deemed necessary. No newborn child can have a pathologic

hemolysis with a hemoglobin stationed at the high level of the newborn, even with dehydration; whereas a falling hemoglobin, especially if rapid, requires very prompt treatment. We know this sign is clinically available and feel that it is of the utmost importance.

There are other aids which may at times help in arriving at a diagnosis, such as family history; however, sporadic cases frequently occur. At this time it might not be amiss to discuss briefly the size and condition of the placenta and erythroblastosis in the peripheral circulation.

Concerning the number of erythroblasts present in normal newborns, the figures given by different authorities are at wide variance. Diamond, Blackfan, and Baty¹ say there are 5 to 10 nucleated red blood cells per one hundred white blood cells counted or 1,000 to 2,000 per cubic millimeter. We feel that this figure is inordinately high. Other authors such as Abt and Nagel,⁷ Simon,⁸ Todd,⁹ and Cummer,¹⁰ give no specific figures but say that an occasional erythroblast may be encountered in the blood of normal newborns during the first few days of life. Sanes and Ryerson,¹¹ in a personal communication on some work as yet unpublished, find that by the end of the third month of pregnancy the erythroblasts have entirely disappeared from placental sections. To quote them, "In the examined fragments of placenta replacement of nucleated by non-nucleated forms took place almost entirely during the second and third months of pregnancy, so that after the third month a normoblast could be found only by inspecting thousands of cells, a proportion unaltered throughout the remaining months of pregnancy. Smears from the umbilical cords of newborns revealed the same almost complete absence of normoblasts."

Diamond, Blackfan, and Baty¹ call attention to the fact that in many of these cases of icterus gravis neonatorum the placenta is noted to be enlarged and edematous. This condition, however, is not constant and it would seem that, for early diagnosis, greater importance should be attached to the histologic section of the placenta, whereas if erythroblasts are found, the infant should be closely watched for clinical evidence of this group of anemias.

To continue with differential diagnosis, syphilis is a disease which can simulate erythroblastosis in *every* minute detail.⁵

It might not be easy to make a rapid differential diagnosis. We all know the variabilities of the complement fixation tests in mothers and babies at the newborn period. The emergency treatment, however, would be the same. It must not be inferred from this statement that "erythroblastosis" is linked up with syphilis. It most emphatically is not.

Congenital deformities must be ruled out, particularly congenital deformities of the bile ducts with obstruction and resulting hyperbilirubinemia. Theoretically the Van den Bergh test should differentiate between obstructive jaundice and hemolytic jaundice, but unfortunately a hemolytic jaundice may cause bile thrombi which secondarily result in blockage causing a direct Van den Bergh reaction thus confusing the issue. Again the hemoglobin estimation is of value in early cases; for a deepening jaundice and a stationary hemoglobin cannot be hemolytic but must be obstructive. Congenital deformities with biliary obstruction are now successfully surgically treated in a goodly number of cases, but these do not require the very rapid and early interference the hemolytic cases demand.

To say as some have, that this hyperplastic-hemolytic group is caused by sepsis is a statement which is borne out neither by clinical nor postmortem experience. As a matter of fact, a general sepsis takes it definitely out of this group. If signs and symptoms are similar the emergent treatment should be the same and the definite proof of sepsis can be established at a later date.

Hemorrhagic disease of the newborn is a condition of unknown pathogenesis. It is not associated with this hyperplastic-hemolytic group for it shows neither abnormal hemopoiesis nor abnormal hemolysis. It is characterized by a prolonged bleeding time and hemorrhages from any part of the skin, mucous membranes, or viscera (lungs, brain, adrenals, etc.). The hemorrhage can be severe, exanguination occurring rapidly. This is the place "par excellence" for intravenous transfusion. We have never had a case in which one transfusion properly performed failed to replace the lost blood and stop the bleeding. This is in direct contrast to the hemolytic group which demands multiple transfusions. We have seen a case of icterus gravis in which the hemolysis was so severe and the resulting pallor under the

icterus so marked that the case was at first taken for a severe concealed hemorrhage. The child was rigid and the enlarged spleen was mistaken for a hematomata of the adrenal. Thus, occasionally these conditions can cause temporary confusion, the diagnosis, however, can easily be cleared up after a more minute study of the case, the emergent treatment being the same.

The real reason for writing this paper is to bring to the attention of the medical profession the treatment of icterus gravis and anemia of the newborn by properly given repeated transfusions. We have been using this method of treatment for the last eight years with uniformly good results in a class of cases in which the prognosis is otherwise poor (icterus gravis).

Diamond, Blackfan, and Baty¹ in their excellent article mentioned briefly the treatment by repeated transfusions and gave a report of several cases in which the amount of blood given was not mentioned. We believe this to be important. Since their publication, there have been several articles written on the subject²⁻¹² which show distinctly that the treatment by repeated transfusions apparently was not sufficiently emphasized, or at least the authors do not appreciate the value of this treatment.

Many authors speak of subcutaneous injections of blood.¹⁴ Others speak of one possibly two transfusions¹² (Sanford) and maybe in insufficient quantity. These are usually accompanied by complete postmortem reports. Others make the statement that they have had no success with transfusions.²⁻¹² (Gruel et al.) In a Round Table Conference on Disorders of Blood and Hemopoietic System led by Dr. Thomas B. Cooley for whom we have the greatest respect, he cited a case of erythroblastosis in the newborn in which the child received seventeen transfusions and still hemolyzed, requiring a splenectomy. The child recovered but died of complications following operation. This certainly is an exceptional case which takes it out of the typical run of cases we are describing. We feel that these cases have a definite period which when safely passed, do not tend to hemolyze. This is similar to a like-period in hemorrhagic disease of the newborn past which these cases do not bleed. In our experience in neither of these conditions is the abnormal tendency carried through into later life. Thus we believe

that no relationship exists between these conditions of the neonatal period and the blood dyscrasias of later childhood such as Cooley's anemia, Jaksch's disease, or familial hemolytic icterus. In Cooley's case, we feel we would have become discouraged after the fifth transfusion and turned the case over to the surgeon, but Dr. Cooley goes on to remark "in another case I should urge immediate splenectomy." This statement seems very radical and unwarranted for three reasons: first, the case from which he draws his conclusions certainly is an exceptional one and not at all according to the usual run of erythroblastosis in the newborn; second, early splenectomy in these cases is unnecessary and would most certainly result in a high mortality; third, properly conducted repeated transfusions have in our hands shown it to be a very successful method of handling these hyperplastic hemolytic conditions.

The method we use in carrying out the treatment is as soon as a case is suspected, we take a hemoglobin, blood smear, and cross agglutinate. Blood testing is advisable in order to minimize unnecessary additional hemolysis.

As soon as the diagnosis is made and the hemoglobin drops, 100 to 125 c.c. of compatible blood is given intravenously by cutting down on the internal saphenous vein at the internal malleolus or half way up the leg parallel and just to the medial side of the tibial border.¹⁵ The transfusion is repeated daily or every other day as indicated, depending on the general condition of the patient and the hemoglobin estimation. If because of insufficient fluid intake, toxemia or dehydration, it seems advisable, a slow intravenous drip can be instituted and if the cannula remains patent, it is often possible to retransfuse without opening another vein. Transfusion replaces the hemolyzed blood with a functionally good blood and stops hemorrhage. The hemoglobin which often drops as low as 20 to 30 per cent should be kept up to 70 or 80 per cent. There must be no discouragement felt if four or five transfusions are necessary, most cases require at least three and usually not more than four.

The rest of the treatment is general hygiene with directions as to food, fluid in take enterally or if necessary parenterally.

To illustrate, we wish to call attention to several cases, not in the usual detailed

manner of review or in tabulated form but from a general viewpoint, since all of our cases have been similar in practically every respect, both in clinical and laboratory findings. Several cases occurring in one family will show this as well as furnishing a striking control series.

This mother has been delivered of six children and has had no miscarriages. The first and third pregnancies resulted in babies who died within a few days of birth. From the description obtained from the mother and from hospital records, these children undoubtedly succumbed to severe cases of icterus gravis neonatorum. Nothing specific was done for these babies as far as treatment was concerned. The second child was a normal infant and to-day is fifteen years old, well and healthy. The fourth child is now eight years old and perfectly normal. She was a full-term female infant weighing 6 lb. 14 oz. From birth the child was markedly jaundiced and appeared drowsy and listless. It vomited part of practically every feeding for the first week. On the eighth day, the child had some bleeding from the mouth and the stools were streaked with blood. It was immediately transfused and given 100 c.c. of whole blood. On the tenth day, petechial hemorrhages appeared, first on the back in the lumbar region and then over various other parts of the body. At this time generalized twitching and jactitations occurred requiring the use of sedatives. On the eleventh day the hemoglobin was 45 per cent (Sahli) and there was one normoblast for every 200 leukocytes counted. A direct blood transfusion of 75 c.c. was given on the twelfth day. Subcutaneous injections of 20 c.c. each were given on the fourteenth, seventeenth, and nineteenth days, and 90 c.c. was given intravenously on the twenty-first day. From this date the child began to improve and was discharged on the thirty-fifth day in good condition.

The fifth child as well as the first and third were not seen by the authors and died on the second day. The autopsy protocol describes the fifth child as being intensely jaundiced, both skin and internal organs. The brain, serous membranes, lungs, mesentery, and skin showed multiple hemorrhages. Icterus gravis neonatorum was assigned as the cause of death.

The sixth child, now five years old, was born at full term, weighing 8 lb. 3 oz., and was deeply jaundiced. From the beginning it regurgitated a great part of its feedings. The bleeding time was markedly prolonged as evidenced by the fact that puncture wounds made for obtaining blood for hemoglobin and blood grouping determinations bled for many hours. The hemoglobin was dropping steadily, going hand in hand with the deepening jaundice. The child was drowsy, listless, in a word toxic. On the second day a direct blood transfusion of 100 c.c. of whole blood was given. The hemoglobin rose and the general condition of the child be-

came improved for three or four days. Then again the toxicity appeared and the hemoglobin began to decline, going rapidly to below 20 per cent (Sahli). Symptoms of respiratory difficulty appeared. On the fourth and seventh day the transfusions were repeated and 120 c.c. given. The child now improved rapidly and was discharged in good condition on the fourteenth day.

Since these cases, we have had the opportunity of treating a series of others occurring sporadically and in families, and the practice has been to transfuse then early and repeatedly. When this has been carried out, the children have improved much more rapidly and have not shown the marked degree of toxicity found in the early cases where transfusions were withheld until the seventh day or later.

In watching these infants we wish to call attention to the fact that the most important guide in treating them is repeated hemoglobin determinations. The deep jaundice masks the degree of anemia and is misleading as to the true state of the infant. Note that in the first and third children, although the hemoglobin was known to be less than 50 per cent, nothing was done. In the last baby the hemoglobin dropped so rapidly that a remarkably low level of 20 per cent (Sahli) was reached before the degree of anemia was realized.

We feel that we cannot emphasize too forcibly the value of early and frequent transfusions for cases in this group of hyperplastic-hemolytic anemias.

ANEMIA OF THE NEWBORN

ROGER H DENNETT, M.D., D.Sc., and LESLIE O ASHTON, M.D.

Department of Pediatrics of New York Post Graduate Medical School of Columbia University

Primary anemia of the newborn can be classified as a definite clinical entity. In practically all the cases reported the following features have been noted. The parents have been in good health, the labor has been normal and spontaneous, and no signs of infection, birth injury, or hemorrhage could be found. The infants appeared vigorous when born, nursed well, and had a normal temperature and except for the development of extreme pallor seemed normal in every other way. Most of the cases recovered both with and without treatment, and no residual effects have been noted in those cases followed over a period of years.

We wish to report a typical case of anemia of the newborn.

CASE REPORT

E. D., born April 9, 1932, a normal male, full-term normal delivery, weighing 7 lb. The mother was well and in good health before and during the pregnancy. The father was also in good health. There is one other child three years of age living and well who has been well from birth to the present time.

E. D. was seen on the first day of life because the nurse observed that he did not cry as lustily as most infants. At that time the physical examination was negative. For the next nine days he seemed fairly active, nursed well on the breast, and had gained back his birth weight.

On April 19, at ten days of age, the nurse reported that during the past twenty-four hours the infant had become very pale. Physical examination showed an infant with extreme pallor, heart and lungs normal, abdomen soft, no masses felt, liver and spleen not felt, there were no cerebral symptoms nor external bleeding. Temperature 99° F., blood examinations showed hemoglobin, 24 per cent, erythrocytes, 1,390,000, white count, 15,600, polymorphonuclear cells, 58 per cent, lymphocytes, 28 per cent, monocytes, 5 per cent, eosinophiles, 9 per cent, coagulation time, 2 minutes, bleeding time, 4 minutes. He was transfused with 100 cc of his father's blood.

On April 21, blood examination showed

hemoglobin, 42 per cent, erythrocytes, 2,600,000, white count 15,600. He was transfused again with 100 cc of blood from the father. At this time a laboratory examination of the stool was negative for blood.

On April 25, blood examination, hemoglobin, 59 per cent, erythrocytes, 2,700,000, white count, 12,000. Transfusion of 100 cc of blood.

On May 1 the nurse reports that the infant at times seems quite pale. Blood examination hemoglobin, 45 per cent, erythrocytes, 2,900,000, white count, 10,900. He was given a fourth transfusion of 100 cc of blood.

On May 14, at five weeks of age, he was discharged from the hospital weighing 8¼ lb. Blood examination hemoglobin, 44 per cent, erythrocytes, 2,600,000, white count, 6,600.

His blood picture after discharge gradually but slowly improved and he gained normally in weight and appeared well. A blood examination on July 28, at 3 months of age showed hemoglobin, 65 per cent, erythrocytes, 3,100,000, white count, 8,900.

March 22, 1934, when nearly two years of age, he had an upper respiratory infection with double otitis media. His blood examination at this time was hemoglobin, 75 per cent, erythrocytes, 4,100,000.

Ecklin¹ reported the first case in 1919. Pasachoff and Wilson² in reviewing the literature in 1931 were able to find twenty-eight case reports. Since 1931 we have been able to find eight new case reports making a total of thirty-six cases reported in fifteen years. Sustrunk's³ case can be classified as doubtful as at autopsy it showed hemorrhages of the renal pelvis and bladder, valvular hematomas, and some icterus. Abt⁴ excludes 3 cases on etiological grounds and one as doubtful as prematurity might have accounted for the anemia. He feels that anemia of the newborn is the most appropriate title for this disease until the exact etiology of the condition has been proved. He objects to the term idiopathic, primary, or congenital anemia. The congenital nature of the disease has not been proved, for these

anemias are of the secondary type. He found phagocytic mononuclear leukocytes in the circulating blood of his case, but feels that this has no bearing on the etiology of the case. Bonar⁵ reported 2 cases born of the same mother but a different father and suggested that maternal transmission might have something to do with the etiology. Segar⁶ reported 3 cases in one family. Except for these two reports there is no reason to believe that the anemia is due to any transmissible parental defect. Pasachoff² brought out the similarity of the blood in these cases of anemia to that of an acute posthemorrhagic anemia. Ehrmann⁷ found increased fragility of the erythrocytes, but this has not been confirmed by other investigators. He reports a case five days old with hemoglobin, 28 per cent, erythrocytes, 1,228,000, white count, 20,500, seven nucleated reds per 200 white cells, coagulation time, 4 minutes, bleeding time, 3½ minutes, and increased fragility of the red cells. He suggests that the increased fragility of the red cells indicates an inherent weakness in the cells themselves. Daldorf⁸ feels that these cases are the result of nutritional deficiencies, and Parsons⁹ also states that congenital anemia is a true nutritional anemia due to deficiency in the maternal diet. This deficiency in the maternal diet may or may not show itself as a nutritional anemia in the mother. He produced milk anemia in rats. Dried brewer's yeast was then added to the milk with a rapid complete cure of the anemia. Litters from these rats, however, were anemic, the hemoglobin ranging from 12 to 25 per cent. Pasachoff and Wilson² reported a case on the fifth day of life with hemoglobin 8 per cent, erythrocytes, 390,000, coagulation time, 5½ minutes, bleeding time, 22 minutes, who died on the fifth day before a transfusion could be given. At post-mortem the predominant feature was a myeloid reaction in the spleen and bone marrow and to a less extent in the liver, and only a slight response on the part of the erythrocytogenic system. There were extremely few normoblasts and no megaloblasts in the circulating blood. Gelston and Sappington¹⁰ reported a case in April, 1930. The blood count on the seventh day showed, hemoglobin, 42 per cent, erythrocytes, 2,300,000, white count, 12,400. On the eleventh day blood examination showed

hemoglobin, 23 per cent, erythrocytes, 740,000, white count, 20,000. The baby received three transfusions of about c.c. each and liver extract daily. At five months of age the blood examination showed: hemoglobin, 78 per cent; erythrocytes, 4,100,000. Except for the fact that the mother had a small abscess ten days before term no other cause could be found for the anemia. They suggested that congenital or primary anemia of the newborn apparently represents some cause acting during the prenatal period which markedly inhibited the production of blood corpuscles and the normal amount of hemoglobin.

We are of the opinion that this is a disease entity distinctive of the newborn but that some of the cases cited in the literature should not have been included. We have seen severe secondary anemia of the newborn with the same blood picture where the anemia was accompanied by pyuria or a focus of infection elsewhere. Such cases, however, are accompanied by fever, and careful examination excludes them from this category. Other infants with a severe anemia have hemorrhages or hemorrhagic disease of the newborn as an etiologic factor. We must be careful to exclude syphilis and hemolytic jaundice. One should also take a careful history on the mother concerning severe acute or chronic illnesses.

The two outstanding features of anemia of the newborn are: the lack of etiologic factors and the tendency to get well even though unassisted in many instances. However, we cannot imagine anyone treating these cases without transfusions. In our case and in many other cases in the literature repeated transfusions seemed to bring little aid in the recovery, but the progress of the anemia without the transfusions must have been different.

Symposium on Cancer

THE RELATION OF THE GENERAL PRACTITIONER TO THE CANCER PROBLEM

JOHN M. SWAN, MD, FACP

Executive Secretary of the New York State Committee of the American Society for the Control of Cancer

It has been well said that the fate of the cancer patient is in the hands of the first physician whom he consults.

The New York State Committee of the American Society for the Control of Cancer has been attacking the cancer problem from one angle, *i.e.*, the angle of public education, for the last seven years. The chief item of our program is to get the cancer patient, or the suspected cancer patient, into the doctor's office at the earliest practicable moment.

In round numbers, there are 150,000 deaths in the State of New York every year. Twenty-five per cent of these deaths are due to heart disease and 10 per cent are due to cancer. Consequently, whenever a patient with subacute or chronic symptoms consults a physician, it seems safe to say that there are thirty-five chances in a hundred that the patient is developing, or has developed, cardiovascular-renal disease or cancer.

The examiner must proceed with the idea of excluding these two common disease groups before he decides that the symptoms of which the patient complains are due to some other abnormality. In other words, he must look upon the patient with an indefinite symptomatology of a subacute or chronic nature in a way similar to that in which the French look upon the individual accused of crime. In French practice, the accused has to prove that he is innocent, in Anglo-Saxon practice, the government has to prove that the accused is guilty. The two problems are entirely different. So, the examining physician must satisfy himself, when he is consulted by an individual who complains of indefinite symptoms, accompanied by a bloody discharge, persistent indigestion, some chronic sore that does not heal readily, particularly about the mouth, or tumor, that he has not to deal with one of the group of diseases above mentioned. We think that the physician who tells the pa-

tient with a breast tumor to wait until the tumor begins to grow, or until it begins to bleed, has not given that patient proper consideration or proper advice. We think the physician who prescribes for a female patient in the age period of the menopause, who has irregular bleeding, without making a pelvic examination is not giving that patient proper consideration. We think that the physician who prescribes for a patient 45 years of age or more, who has complained of indigestion for a considerable period, without urging him to have a gastro intestinal x-ray study, is not giving that patient proper advice.

We are continually receiving letters from people in various parts of the state asking our opinion concerning concrete cases of illness. It might be well to read one such letter.

'My sister, a young woman of 29 years, suddenly developed a lump in her left breast about one year after her little girl was born. She had it examined and was told it was a tumor and should be removed. She went to a doctor who claimed to be able to dissolve it. After wasting six weeks with him it became larger and more painful and he stated it must be operated at once. She went to a specialist who removed her entire left breast because she had a malignant tumor.

She seemed to feel better for about five weeks when she noticed a slight lump on her left shoulder. The doctor immediately removed same and stated it was a small tumor and perfectly harmless. It is now three months since the first operation and she has been told to get x-ray treatments on the left side of her body where she has been operated on. It weakened her heart, and after seeing another doctor it seemed her thyroid gland had become enlarged due to her extreme nervousness. She has to go for these x-ray treatments every other day for six months and then be under observation for two years.

After spending a considerable amount of money the poor child feels very miserable. She has a very dizzy feeling in her head. Having two children she has more than her hands full for a person in good health. Won't you please tell me what she can do to become well, what doctor she can go to in order to get the right kind of advice."

This letter is an excellent example of the uncertainty surrounding the cancer problem. It indicates the lack of information conveyed to the patient or to her family concerning the progress of a concrete case of illness. It reveals the manner in which many lay people repeat opinions given them by physicians. It also shows the undecision that patients and their families exhibit in the case of serious illness, probably the result of ignorance and alarm.

But aside from the layman's attitude, what is to be said about a physician who will tell a patient that he can "dissolve" a breast tumor? What is to be said about a physician who will advocate x-ray treatments every other day for six months as a method of postoperative treatment for cancer of the breast? What can we say

about a physician who will undertake to give postoperative irradiation with roentgen rays with an equipment suitable for diagnostic procedures? Postoperative roentgen therapy requires an equipment of 200,000 volts capacity.

Let the first sentence in this short discussion be repeated: "The fate of the cancer patient is in the hands of the first physician whom he consults."

We feel that it is incumbent upon the general practitioner to study the natural history of cancer and try to understand it. When difficulties arise in the understanding, as they will, he should be willing to seek advice from those who have studied the subject longer, and consequently may be presumed to be able to transmit the knowledge available.

THE RELATION OF THE PATHOLOGIST TO THE CANCER PROBLEM

STEPHEN H. CURTIS, M.D.

Pathologist, Leonard Hospital, Troy

The relation of the pathologist to the cancer problem is somewhat like that of the navigator aboard ship. The navigator with his nautical instruments plots his course, thus assisting the pilot in guiding his ship. The pathologist with his laboratory equipment is able to make a differential diagnosis of the tumor, thus assisting the clinician to pursue the proper course in the management of his patient.

At this time we are all particularly interested in the early diagnosis of cancer, believing that our hope of greatest accomplishment lies in this factor. The general practitioner or family physician is the one most likely to see the patient first. It has been said that the ultimate fate of the cancer patient is in the hands of the first physician who sees him and if the doctor does not recognize his responsibility, the chances for saving life are greatly decreased.

In the first place, it is essential to differentiate between malignant and benign tumors. This may be difficult and uncertain in the gross, requiring two other essentials: a microscope and familiarity with histopathology. This is the rôle of the pathologist. Bloodgood has said that a good surgeon "feels more comfortable to have a pathologist at his elbow" when in the operating room. In order to obtain material for examination, a biopsy is performed.

If an immediate report is desired, a section of the tissue is made by the freezing method. It takes five to fifteen minutes to cut, stain and examine the section, and the patient may be kept under a general anesthetic during this time. If a little more time can be spared and the anesthetic is discontinued, the acetone method may be used. This method requires twenty-four hours but the structure detail of the tissue is apt to show more clearly than by the freezing method. This is particularly true of uterine curettings and tissue of very fine texture.

There seems to be some misunderstanding about biopsy as there are some clinicians who persist in adhering to the belief that it is a dangerous procedure. At the Institute for Malignant Diseases in Buffalo, over seven thousand biopsies have been done and it is reported that no case has been observed in which any deleterious effect was noted. Of course, the proper technic must be followed. Simpson states that they have cut into tumors on their mice, cut out parts, and studied them. Examination of these mice after death shows no increase in metastasis or increase in the growth of the tumor. Bloodgood has often stated that every breast tumor and every bone tumor should be biopsied and clearly diagnosed before any line of therapeutic procedure is considered. The experience of Ewing, Cutler, Geschickter,

and others, all favor the use of biopsies. In our own experience at the Leonard Hospital we have observed no evidences of metastasis or expansion in growth following biopsy.

In cases of benign tumors complete extirpation usually cures the case unless there is some other complication. In these benign tumors, radical operation is never indicated and should not be done. In the cases of malignant tumors, there are several factors to consider before deciding on procedure. First the tumor is to be classified as to structure, such as carcinoma, sarcoma, and the like. Then it must be graded as to its degree of malignancy. This depends upon the cell structure of the tumor and its radiosensitivity. Not all tumors lend themselves readily to this type of differential diagnosis but there are few in which it is not of valuable service. The largest number of carcinomata fall in the intermediate classes of moderate, average malignancy and radiosensitivity, probably about 75 per cent of cervical and breast cancers fall in these classes, and in the remaining 25 per cent the finest diagnostic distinctions become paramount in the prognosis and choice of treatment. In cancer of the body of the uterus, the variations in malignancy become very much greater, and differential diagnosis is almost indispensable. The same holds true in tumors of bones, nerve trunks, secreting glands, bladder, larynx, endocrine glands, and so forth.

These facts about the tumor are included in the report to the clinician, who being trained to interpret them, is able to decide on his subsequent procedure. In addition to the histological report on the tissue, there are other laboratory procedures which have an important bearing on the diagnosis. Radiograms properly interpreted are very important. Wassermann tests should be made in all cases. In bone

tumors, the presence of Bence Jones bodies in the urine is considered almost a positive finding in cases of multiple myeloma. In cases of osteitis fibrosa cystica, the blood chemistry findings, particularly those involving the calcium metabolism are essential to make the correct diagnosis. In tumors of embryonal origin—teratomas, seminomas, choriomas, and the like—the diagnosis is greatly aided by the reaction of the Aschheim Zondek test. Likewise the prognosis may be determined after treatment in these cases by the variation in this reaction. Examination of the stomach contents for blood bacteria and acidity aids in the diagnosis of cancer of the stomach, likewise examination of the stools for occult blood in cancer of the intestinal tract. These findings along with radiograms are invaluable in establishing the diagnosis in these cases.

A word should be said about biopsies in tumors of the cervix, rectum and prostate. In the cervix and rectum, a biopsy may be made safely with a cautery or radio knife. In the prostate, it may be made by the perineal stab method, and the shreds of tissue thus obtained spread directly on a glass slide and stained and examined. Dr. Ferguson told the author the other day that at the Memorial Hospital in New York, their biopsy diagnoses were found to be correct at subsequent examination in over 90 per cent of their prostate cases. It is obviously helpful to the clinician to know with what he is dealing before he begins his therapeutic procedure.

One cannot emphasize too strongly the importance of obtaining a correct diagnosis of the tumor early. Upon this rests the therapeutic procedure, extirpation, radical dissection, and amount and kind of radiation. Ewing says that a correct laboratory diagnosis is the most essential factor in the management of the cancer problem.

THE RELATION OF SURGERY TO THE CANCER PROBLEM

PETER L. HARVIE, M.D., F.A.C.S.

Troy

Thousands of cases of cancer are cured each year through surgery, and thousands more *could* be cured if physicians and laymen were quicker to recognize the disease in its early stages and more optimistic in their attitude toward surgical treatment. Statistics show that in the United States

and Canada there is an approximate annual death of 150,000 cancer cases, and that of this number at least a third might be saved if the disease were recognized early enough and properly treated.

I would refer pessimists in the medical profession to the statistics of a great

organization like the Mayo Clinic. Here thousands of patients are expertly examined yearly with the result that a large number of cancer cases in early stages are picked up, often where least expected. The relatively high percentage of cures effected by the clinic by surgical treatment, especially in varieties which are locally rarely seen at a sufficiently early stage to operate with any expectancy of cure, should have a good psychological effect on the pessimist.

While radical surgery is the best treatment in the majority of cancer cases, there is a group of cases which at this time are universally considered incurable. In this class are cancer of the esophagus, of the cardiac end of the stomach, of the pancreas, of the gallbladder, and of the lung. Cancer of the cervix is generally treated with radium, although if the Schiller test proves successful for early diagnosis, we may return to surgery in this important field. Buccal as well as urological cancer is usually treated with a combination of radium and surgery, and skin cancer study shows about equally successful results from both methods. When surgery is employed in this last group of cases, it is well to remember two things: first, to be sufficiently radical, disregarding the cosmetic result; secondly, to keep well away from the zone of growth when using local anesthesia. To illustrate the first point, the author remembers a case he had a number of years ago in which he removed an epithelioma of the face. He was very proud of the fact that he kept the scar within a wrinkle so that it was practically invisible. Two months later a recurrence humbled his pride. As to the second point, he once had a recurrence along a needle puncture following an operation of a large epithelioma of the forehead.

We have now mentioned the group of cases in which radium or x-ray is used alone or in combination with surgery, and the class of cases which are, up to date, considered incurable. We now come to a third class, those cases which might have been curable had they been treated early enough, but which have become inoperable by the time they come to the attention of a surgeon. A case is generally considered inoperable where the growth has metastasized to some other organ. The author believes that almost every case of cancer should have some form of treatment, if not

with the idea of cure, at least with the thought of making the patient more comfortable. Nasty sloughing masses can often be converted into clean granulating wounds by free use of the cautery. Deep x-ray and radium often help locally as well as generally in controlling pain and bleeding. At one of the clinics resections of the stomach were done where there were metastases to the liver. The theory is that the removal of the primary growth slows up the process and at the same time relieves the local stomach symptoms. Treatment of so-called inoperable cases will increase operative deaths—but what of it! Every once in a while we will be able to effect a cure at a time when we least expect it.

A proper sequence would now bring us to a discussion of the surgical treatment of curable cases, but unfortunately the author knows very much more about cases which have been brought to the surgeon too late to be cured. It is this very fact which the author considers of most interest to the local physician. In the majority of these cases the individual has not sought medical attention until the condition was beyond the favorable stage for cure. A careful yearly examination would probably have meant reaching the cases in time.

In reviewing a rather incomplete list of malignant cases which have been under the author's care from the beginning of 1923 through 1932, he finds that he has dealt with about 108 cases, three-fourths of which have occurred within the last four years, and 20 in the last year. Certain facts of these cases are very striking.

Of some 25 breast cases, only one was doubtful enough to require a biopsy to make a diagnosis. In 90 per cent of the cases there were palpable axillary glands. In this group, 2 patients have lived for five years and one for nine—all 3 being elderly women. Most of the cases have been seen in the last four years and are therefore not qualified for discussion. Two distressing cases were in graduate nurses. One presented herself for operation with an absolutely inoperable local tumor and spinal metastases. The other had been advised to have her breast removed a year before she came for operation. By disregarding all prescribed skin incisions and making an adequate excision with no thought as to the closure, the author has reduced the local recurrence to almost nil. Recently we have

been using the actual cautery, employing the technic of Dr. Scott of Temple, Texas, with the hope of preventing distant metastases. It is too soon to say whether or not this will improve results. We have used very little x-ray in these cases although the immediate results are often very striking. According to Harrington of the Mayo Clinic, x-ray is of doubtful value in cases of high malignancy and of no value in those of low. The author would like to emphasize here the need for radical surgery in breast cases because recently there has been a tendency, particularly in low grade malignancy, to do conservative, incomplete, rather than the time-proven radical operations. Statistics prove that the highest percentages of cures are in that class of cases where there is no nodal involvement and where a primary radical resection is carried out.

In 15 cases of cancer of the lower bowel, the author saw the patients for the first time—with two exceptions—when they were suffering from acute intestinal obstructions which necessitated immediate intestinal decompressions, often blind cecostomies. Resection was later attempted successfully in 8 of these cases. Of this number only 2 are now alive and they have not yet passed the five-year period. In the other 6 cases immediate results were satisfactory, and if they could have been operated earlier, there is a fair chance that the patients would have survived the five-year period. In the remainder of the cases no attempt at resection was made as they were hopelessly inoperable.

Of 10 cases of cancer of the stomach, only 2 were operable. One of these, a leather-bottle stomach with numerous large glands in the gastrohepatic omentum, was practically resected in toto. Although this patient is still alive at the end of two years, she is obviously suffering from further trouble.

There were 15 cases of malignancy of the uterus, including 2 chorio-epitheliomata which the author has lost track of. There were 3 cases of carcinoma of the fundus and the remaining 10 were carcinoma of the cervix. Although the first 5 cases mentioned were operated on by complete hysterectomies, only one carcinoma of the cervix was operated on, that of a young woman of 38, para two, who was referred to the author for cesarian section, the reason being a dystocia due to a rigid cervix

caused by a squamous-cell carcinoma. The author delivered a living child by cesarian section, at the same time performing a pan-hysterectomy. The woman shows no sign of recurrence at the end of three and a half years. The other 9 cases were referred to Dr. Carey for radium treatment.

The rest of the author's malignant cases constitute a varied group. Seventeen were malignancies involving the genito-urinary tract. Of these, 2 involved the kidney, 6 the bladder, 8 the prostate, and one the testicle. One prostate and one bladder case lived for five years or longer. Two other cases of carcinoma of the prostate and one of the bladder, and the case of sarcoma of the testicle are still alive but have not passed the five-year period. The 37 remaining cases are scattered, only 4 of them being epitheliomata, a small proportion when considered in the light of the numbers which were formerly treated by surgery.

Of the prescribed five-year cures there are: breasts: one ten years, 2 five years; one prostate, seven years; one cancer of the fundus, nine years; one malignant papiloma of the bladder, nine years; one so-called cancer of the appendix, five years (the author has had three of these cases, all of a very low-grade malignancy). Furthermore since 75 per cent of the considered cases have occurred within the last four years, there are a good number that the author hopes will join the five-year group.

As time goes on, we see more and more cases of malignancy, but the discouraging fact is that their operability does not seem to be increasing. This means that our attempts at cancer education of the general public has been inadequate locally and that our general practitioners are not referring cases early enough for successful surgery. The answer would seem to be an insistence by all family physicians on at least a yearly checkup, particularly of patients approaching the cancer age and an insistence that every suspicious symptom be thoroughly investigated.

We should all talk a little more about the striking cures of which we know and less of the dismal failures. Let us establish in the lay mind a consciousness that cancer is curable. With hope in their minds instead of terror, patients will cease to delay until too late to present themselves for diagnosis and treatment.

THE RELATION OF PATHOLOGY TO SURGERY
IN THE CANCER PROBLEM

RUSSELL S. FERGUSON, M.D.

Memorial Hospital, New York City

There are two phases of the relation of pathology to surgery in the cancer problem. The first is general and related to the matter of progress in diagnosis and treatment along broad lines. The other is individual and concerns the practicing surgeon and his patients.

One has only to enumerate a few of the achievements of the past three decades to secure an insight into the important influence of pathology on cancer surgery. The removal of the endothelial myeloma from the large group of bone tumors, regarded exclusively by the surgeon as problems for amputation, was due first, to the empiric observation that the tumor yielded to treatment by irradiation; second, to the classical study of Ewing on the structure of the tumor; and, third, to the application of these two findings to the matter of radiologic diagnosis and therapy. No one now regards endothelial myeloma of bone as a surgical problem.

Teratoid tumors of the testis and ovary are susceptible to diagnosis without surgical biopsy or exploration. Careful study of the pathology of these tumors and of the effects of irradiation on the tissue have definitely proved that the only possible means of control lies in irradiation and not in surgery. The mass of evidence that has accumulated in the past twenty years with regard to the effect of x-ray and radium on cancer of the cervix proves the superior results to be obtained by these agents. This is entirely due to the careful study of the gross anatomy of the disease, its natural pathogenesis, and the effects of irradiation on the tissue in the laboratory. The Wertheim operation is definitely discarded by foremost authorities. Present-day problems yield with somewhat greater ease than formerly because of a broader knowledge of the nature of radiosensitivity and radio-resistance of different types of cells.

Extrinsic tumors of the larynx, the author feels sure, will soon become another lost possession of the surgeon due to the fact that the structural features of the tumor suggested to Coutard that the tumor was sufficiently radiosensitive to yield to adequate irradiation. His technic of di-

vided doses of x-ray over a long period of time is now being employed with excellent results in all large cancer centers. The figures at the Memorial Hospital show a salvage of 28 per cent of these cases, as opposed to 5 per cent when surgery was the treatment of choice. The principle underlying this technic is applicable to a wide range of neoplastic disease.

The intensive study of carcinoma of the bladder now being conducted by the American Urological Association through the medium of its Bladder Tumor Registry is a study, pure and simple, of the relation of the pathology and natural history of this disease to the results of surgical and irradiation treatment. The weight of evidence of the material now at hand already tends to throw light on the chaotic state in which the urologist finds himself in the matter of selection of treatment. It is evident that conservative surgery plus the implantation of gold seeds of radon in adequate doses does achieve, in the hands of the average urologic surgeon, better results with less risk than may be obtained by extensive resections or cystectomy.

The dearth of real knowledge of the natural history of neoplastic disease among surgeons is rapidly becoming a thing of the past. This is due in one sense to the appreciation of the experienced surgeon that his results in cancer surgery are not what might have been expected if the conception of radicalism in the removal of cancerous tissues really fits the gross anatomy and cellular pathology of the disease. Another influence has been the wide dissemination of knowledge through the growth of postgraduate schools of surgical pathology, such as Bloodgood's at Baltimore, and of the increasingly high standards of pathology as practiced by the pathologist in the small hospital. Surgeons of experience have taken a renewed interest in the pathological laboratory and seek consultation with the pathologist both with regard to their plan of treatment and to the result obtained. In the heyday of radical surgery few surgeons could be found who could accurately define the chronology of growth in a given tumor and the methods by which the growth might ex-

tend or metastasize. Many patients were operated upon for the removal of a primary tumor when widespread metastases existed.

The author believes that the results of treatment in neoplastic disease will improve in direct relation to the acquisition of a

working knowledge of surgical pathology by surgeons in general. Each individual surgeon will improve his own work by maintaining a file of sections on his own tumor cases and by conference and study of these sections with the hospital pathologist as the cases come to hand.

THE DETERMINATION OF RADIOSENSITIVITY

ELIIS KALLERT M.D.

Ellis Hospital Laboratory, Schenectady

Many years ago it was customary for microscopists who examined fresh stained or unstained, bits of tumor tissue, to venture not only a diagnosis but also an opinion as to the degree of malignancy of a given tumor. Since the advent of radiotherapy and radical operative procedures such opinions have become of great value and at times essential. The subject received considerable study by Broders who has attempted to classify squamous cell carcinoma of the skin and mucosa. Briefly stated, Broders classifies such tumors into four grades, in which Grade I is the slowly growing, pearl-forming type of tumor, and Grade IV, the rapidly growing, infiltrating, nonpearl forming neoplasm, bearing but slight resemblance to the epithelium from which it arises. Similarly, adenocarcinoma has been so classified.

It is believed by some pathologists and surgeons that this grouping of tumors tends to make prognosis more precise. Tumor cells usually resemble those of normal adult tissues when they are spoken of as highly differentiated and are slowly growing, or the tumor cells become anaplastic and revert to the embryonic type of cell when they are spoken of as being poorly differentiated and are usually highly malignant. Between these two extremes lie many intermediate forms, and it is these poorly defined tumors which reduce the value of the method of grading.

One of the important results of the minute study of tumor morphology has been to indicate those tumors which are sensitive to x ray and radium, and those which are not sensitive to radiation. By the term sensitivity, we mean that the tumor tissue will retrogress or disintegrate under the action of x ray or radium, and the surrounding tissues remain normal. Experience teaches that all tissues, normal

and abnormal, may be injured by radiation, but that certain tissues, notably lymphoid tissue and bone marrow are much more sensitive than others. Among the tumors we find that those neoplasms which grow slowly, metastasize late, the cells of which are fully developed, resembling the adult type of cell and tissue, are not sensitive to radiation. Those neoplasms which grow rapidly, metastasize early, and are very cellular, with large nuclei and many mitotic figures, and which lack differentiation so that they bear but little resemblance to the cells from which they arise, are usually sensitive to radiation.

This factor of sensitivity is best exemplified in epidermoid carcinoma of the skin, mucosa, and cervix. The type of cancer corresponding to Grade I in which the prickle cells are well developed, pearl formation present, mitoses few, invasion slight, will be found to be resistant to radiation. Cancer in corresponding locations but without pearls or definite prickle cells but with distinct squamous cell arrangement, prominent nuclei and nuclear figures will be sensitive to radiation. It is by virtue of these details, all too briefly enumerated, that the pathologist is enabled to grade tumors and venture an opinion as to their response to various forms of radiation.

Adenocarcinomata of the breast, the gastro intestinal tract, the uterus, and other organs are insensitive because of their tendency to differentiate into the mature type of tissue. The underlying factor responsible for radiosensitivity is the nucleus of the cell, and in general the larger the nucleus, and the more abundant the chromatic substance, the more readily injured is the nucleus by radiation. Since cell growth and multiplication are dependent on the nucleus and in rapidly growing

tumors the nuclei are obviously hyperactive, they are made more susceptible to the action of radium and x-rays. This explains the great sensitivity of the lymphoid tumors, the leukemic processes, and such bone neoplasms as the Ewing tumor.

The method of grouping tumors, while of limited value in prognosis, becomes a distinct asset in recording those neoplasms likely to respond to radiation and tends to

bring about some degree of uniformity in the art. Thus a patient may be spared a mutilating operation if a preliminary biopsy is performed when practical, and the sensitivity of the tumor estimated. But here again it must be stated that the principles above reviewed are merely general, that there are many exceptions, and that the only accurate means of determining radiosensitivity is to expose the tumor to radiation and note the result.

THE RELATION OF RADIUM TO THE CANCER PROBLEM

H. W. CAREY, M.D., F.A.C.P.

Troy

To-day, as a result of a 30-year study of the action of x-ray and radium upon tissue, we are able to measure the dose of radiation with a considerable degree of accuracy.

In this paper, the term cancer shall include all types of malignant growths, and the term x-ray is used to mean the so-called deep x-ray from machines capable of generating 200,000 volts or more. These machines will deliver penetrating or gamma rays in sufficient amount to destroy malignant tissue anywhere in the body. The ordinary photographic x-ray machine will not deliver gamma rays in sufficient amount except for superficial lesions.

By radium is meant not only the salt of the element itself but also the gas or emanation from radium in solution. This is named "radon" and is used in the form of minute hollow tubes of gold or platinum in which the gas is sealed. Gold and platinum is used to screen or shut out the short burning rays of the radium and for this reason causes no sloughing. These implants, as they are called, are inserted or buried in malignant tissue and the rays given off destroy it. They mark a great improvement over the steel needles and glass implants formerly used.

When radiation therapy is considered or advised, a number of questions arise in the minds of physicians and patients. How much good will it do? What are the chances of getting well? What kind of growths respond to it? Is radium better than x-ray or vice versa? Is it painful? And so forth.

We can answer these questions much more accurately and precisely now than we could 15 or 20 years ago. Like many

other new methods of treatment, the value of radiation therapy first with the x-ray, then radium, and finally deep x-ray, was grossly exaggerated. The enthusiasm of this early period has been tempered by experience and a vast amount of research so that we know now that radiation has its limitations and what the limitations are.

It is possible, moreover, to tell in advance with considerable certainty what types of cancer will respond well to radiation, what types can be completely eradicated, and what ones palliated. This response to radiation is dependent upon a number of factors, the most important of which is radiosensitivity. It has been known almost from the start of radiation that some cancers seemed to respond much better than others. This phenomenon was supposed to be due to greater sensitivity of pathologic cells and tissue, that the radiant rays picked out the pathogenic cells and destroyed them, leaving the more resistant normal tissues unharmed.

This is only partly true. We know now that it is the young, immature cells that are radiosensitive while the mature, adult cells are more resistant. Furthermore, those cells that have a short life cycle are sensitive, so that immature cells with short life cycle are most radiosensitive. These two factors determine the radiosensitivity of any tissue, and we have learned that each tissue of the body has a specific radiosensitivity varying within narrow limits.

All the tissues in the body are vulnerable to radiation if the exposure is sufficiently intense. Within therapeutic limits malignant new growths composed of immature cells with short life cycle are particularly

sensitive to radiation. For this reason growths due to lymphosarcoma, Hodgkin's disease, lymphatic and myelogenous leukemia, disappear with remarkable rapidity. They are, however, exceedingly difficult to eradicate completely because metastases develop so early and are so widely scattered in the body.

The accessibility of a growth has considerable bearing on its successful radiation. This means not only its position on the body surface but also its depth or the amount of healthy intervening tissue. When radium or x-rays have to penetrate a thick layer of healthy tissue to reach the growth, the problem of the radiologist is to deliver a lethal dose to the growth without injuring the intervening tissue. New growths in the brain, chest, and abdominal cavity are difficult to treat for this reason.

Metastases of malignant new growths are in reality the *problem* in all forms of cancer therapy. Take out of the picture this peculiarity of cell transference or of the transferred cell to multiply in malignant growths, and the problem becomes easy to solve. The development of metastatic growths adds greatly to the difficulties of radiation treatment, yet even here we know in advance from experience in what types of growth metastases develop earliest and where they are most likely to occur. As a rule, the metastases have the same sensitiveness to radiation as the original growth, but their location may make them less accessible. There is one notable advantage in radiation so far as metastases are concerned: that is, they may be anticipated and the regions where they are most likely to occur may be radiated before there is any clinical evidence of their presence.

One other factor, and the most important of all, is the length of time the growth has existed. As a corollary this implies the size of the growth. It is axiomatic that the earlier the growth, the more successfully it can be eradicated. Growths of long standing usually are large, involve important contiguous structures and there are metastatic growths. Radiation here can be only palliative at best.

Having in mind these general considerations, there is still the question of what kind of radiation should be employed—x-ray or radium, or both. Dr. Howard

Kelly stated years ago that radium radiation could be used to best advantage when the radium could be brought into direct contact with the growth. On the other hand, when the area to be radiated is large or the growth deeply placed, deep x-ray is better.

To be specific, cancer of the skin and mucous surfaces of the body is particularly well adapted to radium or radon radiation. Ninety per cent of skin cancers can be eradicated in this way. In the author's series of 65 skin cancers, 45 were treated five or more years ago, and of these 39 are living and well, and 6 have died. Three of these were far advanced when the treatment was undertaken.

Cancers of the lips, tongue, tonsils, larynx, jaw, antrum, bladder, prostate, penis, vulva, clitoris, cervix uteri, and rectum are suitable for radium irradiation.

In cancer of the uterine cervix, radiation has become the method of choice. Early cancers of the cervix are rarely seen. Many that appear to be early have already developed metastases. Radical removal by the method of Wertheim is attended by a mortality rate of 20 to 25 per cent, while there is no mortality with radiation. If radical removal is undertaken, radiation should follow without exception. In the author's series of 76 cervical cancers, 58 were treated over 5 years ago, and 10 are living and well. In the entire series only one could be classed as early. Curiously enough, 2 other living cases were radiated after surgical removal—one, eight years ago, the other, six years ago.

Cancer of the lymphatic glands, lymphosarcoma, Hodgkin's disease, lymphatic and myelogenous leukemia respond well to either radium or deep x-ray. The location of the lesion determines which can be used to best advantage. On the other hand, malignancy involving large areas or metastases scattered widely as in breast cancers and cancer within the abdominal cavity are more effectively treated by deep x-ray. Radiation of the marrow of the long bones in leukemia, and cancer of the lung, belong in the field of x-ray.

There are many situations calling for a combination of surgery with x-ray. It is better for surgery to precede radiation, although this opinion is not held by everyone. In breast cancer after extirpation, every patient should be radiated by x-ray, no matter whether the growth is early or

advanced, whether metastases are found or not. Surgical extirpation of cancers within the abdominal cavity should be followed by x-ray in most instances.

One of the most important uses of radiation is palliation. With our hopes fixed on complete and permanent cure as the primary objective, we often forget the merciful effects of palliative measures. With such a large percentage of our cancer patients in the advanced stage, any and all measures that will make the last weeks and months of life more bearable is decidedly worthwhile. In advanced, inoperable breast and uterine cervix cancers, this can be done. Offensive discharges and ulceration may be controlled. In many intra-abdominal cancers the same is true.

The after effects of radiation are of some importance. The cosmetic results about the face where radium is generally used are remarkably good. There is practically no scarring when used about the lips, nose, or eyes, and there is no disfigurement. Both radium and x-rays can be applied without a general anesthetic in all

but a few situations, and there is practically no convalescence. Hospitalization as a consequence is short and in many instances is not necessary at all. Finally it is attended with a negligible mortality.

SUMMARY

1. Radiation of malignant growths has been accepted as a most valuable means of treatment the world over, both alone and in conjunction with surgery.

2. Successful treatment depends upon the early detection of the growth, its accessibility, its radiosensitivity, and the presence or absence of metastases.

3. Radium or radon is best used in growths of the body surfaces where it can be brought into direct contact with the growth and when the growth does not cover too large a surface.

4. X-ray is best used when the growth is beneath the body surface or when it covers large areas of body surface.

5. As a palliative measure, it contributes greatly to the comfort of those who are incurable.

THE RELATION OF RADIATION TO THE CANCER PROBLEM

ARTHUR F. HOLDING, M.D.

Albany

There are two points about treatment which have not been covered in this symposium: expense and electrocoagulation.

It is a regrettable economic fact that most new scientific medical discoveries and inventions increase the already high costs of treatment. In scientific medicine there is a constant temptation to increase our overhead by acquiring expensive new equipment which will never liquidate itself. Common examples of this are electrocardiographic equipment, audiometers, slitlamps and most outstanding of all, radium and x-ray apparatus.

At the Clinical Congress of the American College of Surgeons in 1930, one of our leading authorities on cancer read a paper on "Cancer Institutes" ¹ in which he said: "Finally, there is one very compelling factor, and that is expense. I think it would be quite questionable wisdom to attempt to establish a Cancer Institute without an endowment of about \$10,000,000."

Of course such arguments defeat themselves by their own immensity. Fortunately

among the leading authorities in cancer treatment are scientists who have been forced to perfect radium and x-ray technics that men of moderate means can utilize provided they will organize themselves in tumor clinics and underwrite the overhead by cooperation instead of individualism.

The radium technic perfected at the Curie Institute at Paris, and rapidly coming in vogue throughout the world, requires small amounts of radium, heavily filtered through platinum, applied for a long time.

An important and recent improvement in x-ray equipment is the valve rectified deep-therapy apparatus. This is noiseless, has no moving parts, runs without motors, produces no sparks in air, is over 50 per cent more effective in delivering a depth dose, causes less roentgen sickness, and can be used to deliver many more R units to a given area of skin with less skin irritation than the old motor-driven rotating switch rectifiers. X-rays heavily filtered can be

safely to deliver three or four times as much x-rays as was formerly considered safe, with a consequent improvement in the percentage of cancer sufferers who may be improved and at times made symptom-free

A consideration of expense of cancer treatment leads us to evaluate the economy and efficiency of cautery and electrocoagulation. While we do not wish to belittle the accomplishments of the more expensive methods of treatment, namely, radium, x-ray and surgery, we are inclined to believe that future generations will see that we have overexploited them almost to the point of neglecting the simpler, less expensive methods of heat or coagulation which are more rapidly carried out and often as effective as more expensive methods.

To use all these methods effectively is necessary in treating cancer by modern methods. No man can be efficient and enthusiastic in using all these methods. Therefore a group attack on cancer is necessary and more effectual than treat-

ment by a single method or a single individual.

In closing, we wish to return to the most important topic in a symposium on cancer "The Importance of the General Practitioner in Cancer," and quote from Dr. W. C. MacCarthy.²

If we wait for the classical textbook signs and symptoms of cancer before instituting treatment, we shall never recognize early cancer, early cancer produces no signs and symptoms characteristic of the disease.

In connection with educational campaigns I would suggest that one or more authorities on the scientific and clinical aspects of cancer be financially endowed to carry on an intensive educational campaign among general practitioners who do not have time to attend medical societies. Whoever undertakes such educational work should be financially independent and free from any criticism of seeking consultation for private remuneration.

Face the facts—*The vast majority of tumors can be controlled if recognized early.*

A DOCTOR'S CREDO

The doctors are doing a great deal of strong thinking in these critical times, and from time to time we find the results of their thought expressed in clear vigorous terms. An address of much power, full of stimulating ideas was presented at the annual secretaries' conference of the Indiana State Medical Association a few weeks ago by our Dr. Nathan B. Van Etten. He closed with these thirteen points of his creed—well worth quoting.

I believe that America needs young physicians who have strong characters and are well educated.

I believe that character should stand first in the qualifications of the medical student.

I believe that the undergraduate curriculum should contain the teaching of clinical medicine only, together with its public and private application.

I believe that the teaching of the specialties should be postgraduate only.

I believe that hospital internes should be assisted in the completion of their education by payment of a small monthly stipend during the period of their service.

I believe that ambulances should be served by mature persons only and that they should be paid for this service. I should like to see this work undertaken at the end of the internship so that there would be six months of ambulance training.

ing in emergency diagnosis which would give the young physician a lively experience in a great variety of situations and a most valuable immediate preparation of his life work.

I believe that the number of licentiates to practice medicine should be maintained at the ratio never higher than one to one thousand of our citizens.

I believe that all tax supported hospitals should admit to beds or clinics all emergent cases of accident or illness regardless of financial status and in addition should admit only those citizens whose indigency makes them public wards.

I believe that tax supported hospitals should open all their facilities to all reputable and competent physicians who live in the tax paying district.

I believe that tax supported hospitals should include in their budgets minimum payment for the services of all physicians in both wards and clinics.

I believe in practicability of a county health unit directed by the county medical society and operating without state aid.

I believe in equal opportunity for all physicians forfeitable only by immorality or incompetence.

I believe that the medical profession in America can and will courageously advance to new heights of distinguished service.

A facetious Congressman, addressing the Kentucky State Medical Association, said that the

doctor's grammar runs something like this: "Positive, ill, comparative, pill, superlative, bill."

PAPER AS A MEDIUM FOR LESS EXPENSIVE CHEST DIAGNOSIS

MARGARET W. BARNARD, M.D.

New York City

During the summer of 1931, in the Chest Service at Bellevue-Yorkville, we were interested in evaluating the various procedures for chest diagnoses—physical examination, fluoroscopy, and x-ray. It was at that time that our attention was drawn to a new paper film which was about to be placed on the market by one of the x-ray manufacturing firms.

After preliminary trials, the National Tuberculosis Association requested the Bellevue-Yorkville Health Demonstration to make a thorough test of the paper films to determine their technical merits. This was carried out as a study of 1,000 cases in which celluloid and paper films of each patient were taken and the findings compared.

The paper film consists of a rather stiff paper coated on one side with an x-ray sensitive emulsion. This is placed in the cassette with the emulsion away from the tube. While it is preferable to have only one screen in the cassette—the one next to the emulsion—the front screen does not materially interfere. The technic will be described later.

The exposed films are clipped in the regulation holders and developed in the ordinary manner. It has been found that the developer made by the same firm is quicker in its action than the solution which was previously used, and causes less softening of the paper. Since this developer is equally good for celluloid films, the simplest arrangement in a clinic where both types of films are used is to have only one developing tank and to use this solution. The question arose whether the paper films would soak up the developer, thereby using more solution and adding to the expense. It was found that an equal number of paper films or celluloid films could be run through a given amount of developer. There was no difference in the amount of solution used. Therefore, in making the exposures, we have become convinced that it is practicable to use paper and celluloid films interchangeably in a clinic with the same apparatus and developing solution.

The developed film is a positive and is read by direct, instead of transmitted

light. It has been our experience that the sense of shadow values on the positive is easily acquired.

In reading the comparative films of the 1,000 cases, the paper films were read first and the findings recorded. These were then checked by the celluloid films. Only 5 cases out of the 1,000 were missed which were of clinical significance, an error of only 0.5 per cent.

In July, 1932, the routine use of paper films was introduced in the District Tuberculosis and Cardiac Clinics at Bellevue-Yorkville Health Center. In about 95 per cent of the cases the examining physicians ask for paper films. Our present standard of decision is that in all cases of manifest disease, routine check-up, pneumothorax refills, and cardiacs, paper is adequate. The celluloid is reserved for cases which require further study, usually for very young children, where the most rapid exposure obtainable is desired.

The introduction of these paper films in the clinics has resulted in a large saving of money without any detriment to the service. The developed celluloid film costs us, at City prices, approximately 60 cents, whereas the paper film costs 30 cents. In these days of the problem of maintaining standards of service in the face of shrinking budgets, this is a significant saving.

These paper films are now on the market and may be purchased in sheets of all the standard sizes.

The x-ray manufacturer, using the rolls of paper film in a special camera, has devised a series of carefully coordinated units of procedure designed to make, develop, identify, interpret, and file radiographs at a high speed, permitting large numbers of persons to be x-rayed in a short time at a very low cost.

The subjects strip to the waist and then put on cotton slips which do not interfere with the subsequent x-ray procedure making it possible for them to wait in large groups without embarrassment. As they file past a typist, seated before a special electrically operated typewriter, each subject steps on a direct-reading dial type of weighing scale, adjacent to which is an

upright standard plainly marked in inches. The typist records on a special card made of lead and cardboard, all data required, such as name, address, age, sex, color, height, and weight. This typed card is handed to the subject who, in turn hands it later to the x-ray operator. These cards can be easily typed at the rate of three per minute.

The subjects then stand in line waiting to be x-rayed. The machinery is carefully shielded, so that no harm can come to those in line. Two technicians are employed, one to place the subject in position, the other to make the exposure.

The radiographic unit consists of a standard x-ray generating equipment and tube, and a new form of magazine cassette designed for very rapid operation (Fig. 1).

The cassette holds a roll of paper film fourteen inches wide and 150 feet long, sufficient to make one hundred radiographs 14 by 17 inches each. Provision is made for changing rolls or reloading in daylight.

The cassette contains a suitable mechanism for measuring and feeding successive portions of the paper film into position for exposure and for placing the intensifying screen in close contact with the sensitized side of the film. But one intensifying screen is used, located on the opposite side of the film from the tube.

The cassette is quickly and easily adjustable in height to suit the subject being x-rayed. A quickly adjustable compression band permits the holding of the subject closely against the face of the cassette. This compression band can be moved instantly to bring it to the proper height on the subject. Actuated by the compression band mechanism is a pointer which registers on a dial the thickness of the chest of the subject and indicates to the second operator the proper amount of radiographic energy to use for that exposure.

The tube support is linked up with the cassette and the compression band in such a manner that the tube is always automatically at the height of the middle of the compression band. No time, therefore, is wasted in adjusting the position of the tube, which is always centered on the vertical median line of the cassette.

Technic.—For the sake of speed in operation, three of the four controllable variables, *viz.*, time, distance, amperage, voltage, have been standardized. The time

is usually 1/10 second (occasionally 3/20 for very thick chests). The distance from the tube to film is 40 inches. The amperage is 100 ma. The voltage is then changed to suit the chest of the subject and varies from 60 to 80 kv.

By means of this coordinated mechanism, designed to simplify the necessary operation of changing films and positioning the subject and tube, it is possible for two technicians to x-ray subjects at the rate of four per minute. A convenient rate of one hundred and fifty per hour can be maintained without any difficulty, over a long period of time.

This speed of taking x-rays would, however, not be of much value unless the procedure of developing and interpreting could also be carried out with equal speed.

Fig. 1.—Radiograph unit for chest.

The finished rolls are taken immediately to the manufacturer and developed in the roll form, fixed, washed, dried, and rolled on a spool ready for interpretation, and returned to the owners.

Viewing Box.—For interpretation, the roll is placed in the viewing cabinet in which the films are properly illuminated through daylight glass. The films are successively turned for viewing. Any abnormalities noted may be marked directly on the film. A convenient and time-saving method of recording film findings is for the interpreter to dictate into such a device as the ediphone, from which the records can be transcribed.

Filing.—The rolls, properly indexed, form a convenient method of filing for large groups, such as school children or factory employees. It is a simple matter to put a roll on the viewing cabinet and run it through to the desired picture. One great advantage is that, while the single

films can be made to burn, the rolled films can be made to burn only with the greatest difficulty and no obnoxious gases are generated. Therefore, fireproof filing is not necessary.

An illustration of the use of this method is the recent work project conducted under the direction of Dr. Shirley W. Wynne, under an appropriation by the State Relief Committee for Medical and Nursing Service. Eleven thousand individuals, 10 years of age and over, from families on home relief in the Central Harlem Health District were x-rayed in six weeks' time, and follow-up clinics for the positive cases and their contacts were established. Since this is an area where the prevalence

of tuberculosis is unusually high and the tuberculosis mortality is several times that for the City as a whole, it was considered of the utmost importance to discover and place under care all cases of tuberculosis which might be foci of infection. However, it seemed an impossible task until this rapid survey method became available.

Enough of these rapid x-ray surveys have now been carried out, so that we are convinced that, if a group of individuals in which there is a high prevalence of tuberculosis can be selected and controlled, this procedure offers the most rapid, efficient, and least expensive means of case finding now available.

THE WORLD'S "BEST PAID MAN"—THE DOCTOR

This rather startling description may cause some of us to glance in the mirror and wonder if the man we see there is really the one who is meant. "The best paid man in the world!" That is the diagnosis of a Virginia physician, Dr. Beverley R. Tucker, in a letter to his state medical monthly. In the first place, remarks this cheerful practitioner, the doctor is required to have an education which will be a benefit and a comfort to him all the days of his life. He wins a degree and attains the honorable title of doctor. He learns to know more intimately his fellow man than anyone else can know his fellow. He gets praise for many things that he does not deserve and providence and disease are blamed for his mistakes. He wins the gratitude of those he serves. His charity work is invaluable to his experience. If he is reasonably conscientious and works reasonably hard, he builds a practice that will insure him a good house,

office, and automobile, and enable him to rear and educate a family and to stand the losses of the inevitably foolish investments he makes. If he has taste for invention, there are innumerable unknown instruments and improvements awaiting him. If he wishes to discover, the laboratory is ready for him. If he likes research, the facilities and libraries are available. If he craves adventure, insidious dangers lurk around him, and there are ever pioneer fields to enter. In his endeavors his government, his community, and his fellow physicians stand ready to aid him. He is an advocate without a jury, a judge without a court, a minister without a surplice, a business man without guile, a farmer whose soil is the human body and whose crops are human health and happiness, and he is a laborer without a boss. The physician is the best paid man in the world.

HARD TIMES AND INSANITY

A striking increase in the admissions to the mental hospitals in the State has marked the years of the depression, reaching an all-time peak in 1933. The sharp rise may be realized when we learn that in 1910 the rate of incidence of mental disease as shown by first admissions to hospitals was 65.3 per 100,000 population; in 1920 it was 69.8; in 1930, 76.6; in 1933, 84.7, the highest in the history of the State.

The annual increase, "with improving business, should be less than it had been during the last four years," says Dr. Frederick W. Parsons, head of the State Department of Mental Hygiene, and he adds that "Even the present year so far shows a reduction from last year of approximately one-third in the rate of increase. It follows that as business improves and family incomes increase, relatives become less reluctant to remove patients progressing toward recovery. These relatives are now able to do what could not be afforded twelve months ago."

Dr. Parsons cited a big increase in admissions in the "alcoholic group" rising to 706 during 1933, which marked the end of prohibition, but

he pointed out that repeal did not come until late in the year.

"The cases of alcoholism in preprohibition days were slightly in excess of 10 per cent," he said in a statement. "The rate began to decline in 1912, falling steadily to 1921, when the low point of 2 per cent was reached."

"Then it began to mount until 1927, when it was 7 per cent. In the succeeding six years it ranged from 5.8 per cent to 6.5 per cent. The postrepeal period has not been sufficiently long to justify predicting the trend."

Discussing the increase in admissions, Dr. Parsons said: "For years New York State did not have sufficient accommodations for its mentally disordered residents and about ten years ago it embarked on a building plan. An overcrowding of 35 per cent has been reduced to 12 per cent."

"Today less than 5,000 more beds are needed, and during the calendar year of 1934 3,500 beds will come into use. Buildings now under construction will supply 3,800 beds in 1935, and 1,000 more beds in 1936."

CASE REPORT

A SECOND ACUTE PERFORATION OF MARGINAL ULCER

EDWARD V DENNEEN MD FACS

Assistant Surgeon Bellevue Hospital New York City

Acute perforation of a marginal ulcer is unusual. Herewith is presented a case of a patient with recurrent perforation of marginal ulcer and with recovery.

This patient, a male 27 years old, was first seen January 30, 1933, when he was admitted to the Fourth Surgical Service at Bellevue Hospital, of which Dr. Carl G. Burdick is Director.

His past history is of gastroenterological importance. In 1928, he first had pain in the epigastrium accompanied by nausea and vomiting after meals. A diagnosis of duodenal ulcer was made and he improved on a Sippy diet. Six months later he was taken to St. Marks Hospital suffering from a severe gastric hemorrhage. A blood transfusion was given and later a gastric resection was performed. At this operation, an ulcer the size of a ten cent piece was found on the anterior surface of the duodenum about $\frac{1}{2}$ inch from the pylorus. There was no perforation. The pylorus, $\frac{1}{2}$ of the stomach, and first portion of the duodenum were removed, the duodenal stump was closed and a retrocolic Polya end to side anastomosis was performed between the stomach and jejunum.

He felt well for two years but in 1932 returned with a severe hemorrhage from a marginal ulcer. Following a transfusion, he felt fairly well, having but slight abdominal pain until May, 1932, when he had a sudden, severe epigastric pain. He collapsed and was taken to the Peoples' Hospital where operation revealed an acute perforation of a marginal ulcer in the jejunum about 1 inch distal to the anastomosis. At that time, no kinking was noticed. The perforation was closed and the peritoneal cavity was drained. Since this operation he has had severe burning pain in the epigastrium, indigestion, belching of gas and severe constipation.

At 4 A.M. January 30, 1933, he awakened with severe abdominal cramps no vomiting but much belching of gas. The pain was cramp like, with intervals of freedom from pain. Physical examination at Bellevue Hospital showed an acutely ill, pale man with a fever of 102° F. pulse 100 respirations 24. General examination was negative, except for abdominal signs and hemorrhoids. The abdomen was not distended, there was a right rectus scar from ziphoid to symphysis, there was board like rigidity, with tenderness greatest in the right lower quadrant, the liver dulness was not obliterated no masses were felt. Emergency x ray examination gave no indication of an intestinal obstruction. White blood cells were 14,600 with 88 per cent polymorphonuclears. Urinalysis was negative. The preoperative diagnosis was acute perforation of marginal ulcer with acute peritonitis.

Operation was performed January 30, 1933, an

upper left rectus incision being employed. There was a large quantity of gastric and duodenal contents in the peritoneal cavity with redness and injection of the peritoneal surfaces. A perforation about the size of a pea was found in the jejunum $\frac{1}{2}$ inch from the margin of the retrocolic anastomosis to the resected stomach this area being covered with plastic material and signs of an early acute suppurative peritonitis of the severity usually found in a ten hour perforation. At the gastrojejunal anastomosis there was a marked kinking. The proximal jejunum had been anastomosed to the greater curvature and the distal to the lesser curvature. The kinking and inflammation probably from the previous perforation of May 1932, left at the present time an inlet to the stomach from the jejunum admitting the index and middle fingers and an outlet from the stomach not admitting the little finger. That is, there was an obstruction at the outlet from the stomach.

Because of the peritonitis no revision of the anastomosis could safely be attempted. The perforation was sutured with dulox, intestine and omentum were sutured over the perforation, and an entero enterostomy done between the proximal jejunum and jejunum about 2 inches distal to the perforation, the anastomosis being 3 inches in length and sutured with dulox. The abdominal incision was closed with one cigaret drain intraperitoneally.

The convalescence was rather uneventful, there being a temperature of 103.5° F on the first day, gradually declining to normal on the seventh day. The patient went home on the sixteenth day on a Sippy Diet, with the operative wound healed.

He was seen in the Gastroenterology Clinic at Bellevue Hospital five times during the early part of 1933 and felt well as long as he adhered to his ulcer diet. On May 22, 1933 a hemorrhoidectomy under caudal anesthesia was performed for bleeding hemorrhoids and a blood transfusion was given for a secondary anemia with 60 per cent hemoglobin. He has gained 20 lb since operation and feels well except when he commits a dietary indiscretion. A gastro intestinal x ray examination was done on January 18, 1934, by Dr. Buckstein at Bellevue Hospital. He reported Gastrojejunostomy functioning. Stoma narrow. Evacuation of gastric contents occurs in spurts. No tenderness elicited.

This case is interesting because acute perforation of marginal ulcer is rare and because it portrays the dramatic possibilities of a peptic ulcer and its complications even under medical treatment and a noncure despite surgical treatment with no assurance that further trouble will not follow.

papers and letters published in the JOURNAL.

EDITORIALS

Is this Criticism Just?

The charge is made by the editor of a radiological journal that few physicians are acquainted with the indications for and uses of radiation therapy. Many of them, he remarks, seem to think that its use is limited to a few diseases and, at that, is only a palliative measure. Even some who have seen what it can do for cancer, he adds, are reluctant to accept it or concede it its just place in the treatment of that disease.

The editor of *Radiology* seems to believe that "the splendid accomplishments in the cure of cancer with radiation therapy, resulting from long and continuous scientific research in the fields of physics and biology, are known to but few physicians." He attributes this condition to the rapid advance in the science of radiology, the construction of x-ray apparatus of greater magnitude and precision, and the practical application of the very short wave lengths made possible by the new and powerful transformers. Then, too, it seems, the radiologists are so hesitant that they do not like to report results until they can speak with surety of "five-year cures."

For this reason the rank and file of the medical profession do not hear a great deal about the excellent results of radiation therapy, while they are inundated with reports of the surgical treatment of cancer, set forth in all the medical and surgical journals.

This critic is especially stirred by a recent symposium on the curability of cancer which played up surgical treatment and rather slighted the treatment by irradiation therapy. He, therefore, proposes to gather and publish the statistics on five-year cures of cancer with radiation therapy, with a résumé of the progress made during the past few years of rapid advance. This will be educative in enlightening the medical profession in general and will also be of value to the radiologists themselves.

There can be no question, of course, that such information will be of value, but is it a fact that the medical profession are so far behind the times as he seems to think? Every doctor, it is true, is not an expert radiologist, but neither is he an expert in every other line. Our medical system is so admirably organized that a specialist in any branch who may be needed is usually within reach, and the general practitioner is accustomed to turn to him. The doctor who encounters a case of cancer turns to the cancer specialist. Is it supposable that a cancer specialist is not familiar with treatment by radiation therapy? Visit all the first-class hospitals from the Atlantic to the Pacific and ask if they do not have departments for treatment by radiation. We may well grant that the doctor may profitably learn more about radiation therapy, just as he can profitably have more knowledge of any kind, but we may equally well maintain that the doctor is aware of its benefits and is ready and eager to use it whenever advised by specialists whose duty it is to know its methods and results from A to Z. The collection and publication of complete statistics and reports on what it has done will be a work of great value and the entire profession will look forward to it with the highest interest and anticipation.

Dangerous People at Large

If we knew that 6,442 persons were at large who were liable to attack their neighbors with knives or axes and inflict dangerous and disabling wounds, the public alarm would be at fever heat, and the police would be called upon to capture them and put them behind the bars. But when we read that in 1933, 6,442 persons infected with syphilis discontinued treatment at the New York State clinics without permission and went out to mingle with society with no restraint, nothing whatever is done about it.

They may have been made temporarily noninfective, but it is considered improbable by the State Department of Health that they have had a sufficient number of treatments to make relapses infrequent. Due to the inadequacy of treatment, it is expected that a proportion will again become infective and through promiscuous habits will spread the disease. Furthermore, figures show that approximately 5 per cent of syphilitics develop paresis or tabes dorsalis. On this estimate some 322 of the 6,442 will become paretics, and the State health authorities reckon that it will cost the State about \$385 per year to care for each of them. Our statistical experts have found that paretics drag out their unhappy existences for approximately 24 years from the time they enter the doors of the state hospitals till released by death, so the cost of maintaining this unfortunate group will be nearly \$300,000. Then in addition the investment for state hospital facilities per inmate is put at about \$4,000, so that the hospital facilities enjoyed by our parietic company will represent an investment of over \$1,250,000.

All because these dangerous persons are permitted to walk out of the clinics at their own sweet will and mix freely in society with no one to exercise the slightest restraint. Far less damage is done each year by mad dogs, by pyromaniacs, by South Sea cannibals, or the head hunters of Borneo, but the facts are not even published in the daily papers, where a calf with two heads gets a place on the front page.

How Denmark has stamped out syphilis was related in an editorial in our issue for April 15. It was done by treating it as we

treat any other contagious disease. We would not dream of letting people wander about the streets with smallpox, scarlet fever, or measles. So Denmark makes treatment for syphilis compulsory and visits infection of other persons with severe penalties. The plan works. The ailment has virtually disappeared. Why not learn something from this example?

Doctors and Narcotics

One in every 1,000 of the population of the United States is a drug addict, according to the estimate of the United States Public Health Service. This would give a total army of some 125,000 victims, a pitiable horde, certain to cause endless trouble, social, criminal and medical, all their lives, and with no sign of decreasing numbers. It is a problem of peculiar interest to the physician, as he may very likely number some of the addicts among his clientele, and has in his hands the power to prescribe or withhold narcotics. It is true that the physician is not permitted to prescribe them merely to maintain the addict's customary use, and can do so only for the cure of the addiction or the treatment of disease, as has been repeatedly declared by the United States Supreme Court, but the borderline is not always clear, and a doctor may often be trapped into granting the wishes of a patient who presents a pathetic plea and a score of ingenious justifications.

What is more, the physician himself, harried and worried, worn down by sleepless vigils and irregular meals, sometimes resorts to the false succor of narcotics, and falls a victim. H. J. Anslinger, United States Commissioner of Narcotics recently addressed the Federation of State Medical Boards of the United States on this subject, one of deep interest to the medical profession. About three years ago he had an informal survey made by the field officers of the narcotic service to locate the addicts among the total number of practitioners or druggists registered to prescribe or dispense narcotics. The names of about 1,700 such registrants were furnished, he says, "most of them being in the practitioner class." This would be about 1 per cent of the profession and would put the United States on a level with Ger-

many in this respect, for, observes Mr. Anslinger, in both countries, according to reliable statistics, one in every 100 of the medical profession is an addict. Germany's general population, on the other hand, has only one addict in 10,000 to our one in 1,000.

The Narcotic Bureau is trying to eliminate the registrants who are addicts, or are engaged in traffic in narcotics by having their licenses revoked by their State authorities. The law now in force in this State and in New Jersey, Florida, and Nevada provides for the revocation of the licenses of physicians convicted of violation of the narcotic law. The Bureau reported to the various State licensing boards the names of 360 physicians convicted of violating the Federal Narcotic Law, 302 others found to be addicts, and 12 accused of gross narcotic irregularities. Only the flagrant cases were reported. Thirty-one of the accused were licensed in more than one state, so that the total number of reports were 705. Of these, 39 had their licenses revoked, 5 were suspended, 24 put on probation, 20 admonished, 66 cases dismissed with no action, and 42 were not licensed.

New York State shows up very favorably in the detailed table that accompanies Mr. Anslinger's paper. Contrasting with States having 30, 40, or 50 reported for narcotic irregularities, this State had only 9—3 reported for conviction, and 6 for addiction—miles away from the "one in 100" pictured in the profession as a whole. Of the 9, but one had his license revoked, 7 cases were dismissed without disciplinary action, and one was found not to be licensed. It would be hard to imagine a cleaner record.

This fine bill of health, however, need not blind us to the perils of the larger general population problem. All efforts so far seem unable to cope with it. Clinics established in New York and other places throughout the country tried the experiment at one time of furnishing addicts with nondiminishing doses, with the idea of giving them comfort and stability, but the plan proved unworkable. Dr. Walter L. Treadway, of Washington, pointed out in the course of the discussion that this

scheme brought on uncontrollable abuses. Addicts swamped the clinics, irregularities crept in, and the federal government had to condemn the practice.

Acting on the same principle, adds Dr. Treadway, well-meaning but misguided physicians have, through sympathy, furnished addicts with drugs to satisfy addiction and subsequently found themselves overwhelmed with individuals demanding drugs. As a result, the physician accidentally finds himself in the position of a trafficker in these substances. The laws of the land have made certain professional groups the custodians of these perilous substances. They have the problem, together with the officers of the law, of eradicating or modifying this evil, if it can be done. It certainly could be in no better or more competent hands, and the earnest efforts now being made may well assure us that on time a way will be found to cope with it.

Vacation Typhoid

There is a tendency to be lulled into a false sense of security by the sharp fall in the death rate from typhoid fever in recent years. We shall do well to remember that the danger is there, just as menacing as ever, and that the death rate for the victim is 100 per cent, no matter how low it may be for other people. Now is the time when families are starting gaily out on their vacations, drinking from strange sources of water supply and milk supply, and bathing in waters filled with all the germs in the catalogue, and it is the duty of the family physician to drop a word of warning.

Automobile touring is growing more and more popular, and the families jaunt from hotel to hotel, or from camp to camp, often without the slightest thought of where the water or milk come from. People who wish to enjoy their vacations, instead of spending the summer in a hospital, should take the trouble to ask a few searching questions about these supplies. If the answers are doubtful, it is perfectly easy to boil the water and to pasteurize the milk by heating it in a double boiler to 145 degrees F. and holding it at that temperature for half an hour. This makes it safe without impairing its taste or digestibility.

Lakes and rivers bordered by summer hotels often receive their sewage, yet are used by the guests for bathing every day, braving the bacilli with the valor of ignorance. Cases are not unknown where hotels discharge their sewage into the same lake where they get their water supply. Protective inoculation is certainly a wise precaution. It should be kept in mind, too, that typhoid immunity usually requires from six weeks to two months to develop its highest efficacy and families going on vacation will do well to start their course of protective inoculations without delay.

Anonymous letters will not be noticed. All communications must carry full name and address of the writer, but these are omitted on request.

NEONATAL MORTALITY

To the Editor:

I was very much interested in your editorial on "The Tide is Rising," in the June 15, 1934, issue of the *NEW YORK STATE JOURNAL OF MEDICINE*. In the June, 1932, issue of *American Medicine* I discussed the "Neglected Factors in Comparing Maternal Mortality Rates," but as a pediatrician I am still more interested in the causes of neonatal mortality. In your editorial you quote Dr. Parran as stating that last year in New York State 3,000 babies died in the first day of life and another 3,000 died in their first month. In a paper on "Some Factors in the Infant Mortality Problem" published in the *NEW YORK STATE JOURNAL OF MEDICINE*, September 1, 1928, I showed that the high neonatal mortality is not due primarily to lack of care and skillful treatment. While the infant mortality during the first year has been reduced more than 50 per cent in the last twenty years, the neonatal deaths remain about the same, because only a small number are preventable with the method now at our command.

Some years ago, Holt and Babbitt reported, in the *Jour. Amer. Med. Assn.*, January 25, 1915, a study of 10,000 consecutive births at the Sloane Maternity Hospital. The neonatal mortality during the first fourteen days was 3 per cent, and half the deaths were ascribed to congenital debility chiefly due to prematurity. There can be no question as to the skillful conduct of labor and the adequate care of the infants. This mortality rate was about the same as for the entire city of New York, and the rate given by Dr. Parran for the State.

The limitations of prenatal care should also be recognized. This together with improved obstetrics will reduce the deaths due to syphilis, toxemia, the accidents and injuries of labor, but a large number of miscarriages, premature, stillbirths, and neonatal deaths cannot be prevented by methods now at our command. A marked reduction will be possible only if there is a change in the character of the mothers, either through an improved type of immigrants or if conception is prevented in the unfit.

CHARLES HERRMAN, M.D.

Books (REVIEWED)

Surgical Anatomy.—By Grant Massie, M.D. Second Edition. Octavo of 458 pages, illustrated. Philadelphia, Lea & Febiger, 1933. Cloth, \$6.00.

The revised and enlarged edition of this work is filled with pithy material of the fundamentals of anatomy, to enable one to appreciate the application as well as the interpretation of anatomical problems which may present themselves in clinical medicine. The book covers valuable information which has been contributed in recent years. The numerous illustrations, many of which are schematic and photographic reproductions in color, render the text most comprehensible.

It is a noteworthy contribution to the surgeon's library, an aid to the general practitioner, and an asset to the student.

JACOB S. BRILLY

The Practical Medicine Series.—Comprising Ten Volumes on the Year's Progress in Medicine and Surgery Series, 1933. Chicago, The Year Book Publishers [c. 1933]. The 1933 Year Book of General Surgery, edited by Everts A. Graham, M.D. 12mo of 326 pages, illus. trated. Cloth, \$3.00.

This is a most satisfactory summation of the advance in surgical pathology and technic of the past year. The avalanche of surgical papers encountered in the medical press of today is carefully sifted and excellent judgment is evidenced in the selection of the material incorporated in this section of the Year Book. The reviewer suggests that every active surgeon browse leisurely through this volume. He will find it interesting and very instructive reading.

GEO. WEBB

The Management of Fractures, Dislocations and Sprains.—By John A. Key, M.D., and H. Earle Conwell, M.D. Octavo of 1164 pages, illustrated. St. Louis, The C. V. Mosby Company, 1934. Cloth, \$15.00.

This work is divided into two sections, Part I relating to "Principles and General Considerations," and Part II to "Diagnosis and Treatment of Special Injuries." The late Chas. E. Dowman has written an excellent section on fractures of the skull. Again and again the authors properly assert that early reduction of fractures and dislocations means easy reduction.

Nonoperative treatment is given first consideration, and the authors resort to open reduction only when other means, including skeletal traction, prove ineffective. The section on treatment in fracture of the neck of the femur is well considered, and it is emphasized that the general condition of the patient is more controlling than the special symptoms of the lesion.

The section on meniscus injury implies that the ordinary operator through a small incision can remove all the offending pathological products, in this respect, however, the authors endow the reader with too much visual or tactile acuity.

This is an excellent volume, especially for the more experienced exponents of traumatic surgery, and the authors out of a very wide experience are to be commended for advocating only those procedures which they have tried and not found wanting.

JOHN J. MOORHEAD

Diet and Dental Health.—By Milton T. Hanke. Octavo of 236 pages, illustrated. Chicago, University of Chicago Press [c. 1933]. Cloth, \$4.00.

For a long time students of nutrition have been concerned with the determination of those substances which are an essential part of the normal diet. Our present knowledge of the vitamins and of the so-called deficiency diseases is the outgrowth of such studies.

The interest of the dental profession in vitamins should be stimulated by the present studies of Hanke on the antiscorbutic vitamin (vitamin C). Dietary studies were made over a period of three and a half years, on a series of 341 children between the ages of ten and seventeen years, at Mooseheart. The results indicated that during the test period the children gained in height and weight at rates not only in excess of those present during the control period but also in excess of the normal rates calculated from the Baldwin tables. Other interesting results were obtained.

The material is ably and readably presented. 68 pages of tables present all the original data, an important and unusual inclusion, 40 plates in color give the salient features of dental pathology and show the observed changes in the teeth and gums. The study is thought provoking and should stimulate work elsewhere to confirm or disprove the author's hypothesis.

LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

Malpractice—A Gratifying Decision by an Appellate Court

In an action defended by your Counsel the Appellate Division of the Supreme Court has just handed down a decision which not only rectifies a gross miscarriage of justice but is also of importance to every practicing physician.

In order to understand the force of the rule, it is necessary to set forth in some detail the facts of this case.

The plaintiff in this case, a man nearly sixty years of age, suffered an injury in the course of his employment through a fall from a scaffold by striking an iron bar which lay across a vat beneath. His employer sent him to a doctor for examination and an operation was advised for a condition of hernia. He was referred to a certain Dr. G., a surgeon, who examined him and found that he was suffering from a direct inguinal hernia on the left side, which required immediate attention, a slight indirect oblique inguinal hernia on the right side, and an umbilical hernia.

It was the opinion of the surgeon that the man's trouble on the right side was not such as to warrant operative interference at that time but that an operation should be performed on the umbilical hernia and on the direct inguinal hernia and that any condition on the right side should await the results of these operations and further observation by the surgeon of the patient.

The surgeon testified that prior to the operation he explained these facts to the patient and told him exactly the nature and extent of the operation to be performed. Admittedly, prior to the operation the plaintiff signed a written consent and the surgeon testified that he saw that written consent before the operation was performed.

Accordingly the surgeon operated on the umbilical hernia and also the left inguinal hernia. No operation was performed on the plaintiff's right side. He had an uneventful recovery and left the hospital in about three weeks' time. He promised to come back to the surgeon for further observation but never did so.

During the trial it was shown that some time later he had arranged for an operation on his right side by some other surgeon and went to the hospital for this operation, although the operation was never performed because the plaintiff would not consent to it, and plaintiff further gave the remarkable testimony that when he went to the hospital he had no intention of consenting to this operation on his right side.

Some time thereafter he instituted an action against Dr. G., the surgeon who operated upon him, Dr. H., one of the doctors who had examined him prior to the operation and who assisted at the operation but did not take any active part in it, and he also joined as party defendants the company which had employed him at the time of the injury and the insurance company which carried workmen's compensation insurance on behalf of the employer.

The plaintiff sought to recover damages against these defendants, claiming in substance (1) that he did not have any hernia on the left side and had not consented to any operation on that side; (2) that the surgeon was negligent in the performance of the operation on his left side; and (3) that the surgeon was negligent in failing to operate for the claimed condition on the right side.

The case came to trial before a Judge and a Jury and upon the trial the court directed a verdict in favor of Dr. H., who had simply made an examination but did not actively participate in the operation. The case was sent to the jury as to Dr. G., the employer, and the insurance company, and the jury returned a verdict in favor of the plaintiff and against all three defendants. From the judgment entered in this verdict all of the defendants appealed to the Appellate Division.

The judgment in favor of the plaintiff was reversed by the Appellate Division with a vigorous opinion in which the court plainly said that the plaintiff's testimony was unworthy of belief; that the surgeon

was fully justified in everything that he did and that as to the employer and the insurance company no liability could attach to them in any event because concededly they had selected a surgeon of recognized experience and ability in operations of this character

On the trial the plaintiff produced no medical testimony to the effect that the defendant physician had failed to follow proper and approved practice. He did produce a physician who claimed that about one month before the operation he examined the patient and found him suffering from an umbilical hernia and a right inguinal hernia, but that he had no left hernia. This doctor, however, did not have any proper experience in the field of hernias. He testified in part

'Q Are you a surgeon Doctor? A When I use a knife, I am a surgeon

Q We want to get some idea here. Do you do surgical work major, you know what major surgical work is? A Do I do surgical work?

Q Yes A No

Q Do you ever operate on hernias? A As an assistant yes'

He further testified in all his experience he had personally operated on only two hernia cases.

Upon the trial the plaintiff was forced to admit that the defendant surgeon had examined him prior to the operation on the left side as well as the right side.

Upon the trial we confronted the plaintiff with a consent to the operation which he was forced to admit he had signed. Although his signature was very legibly written exactly on the line provided by the hospital blank, he testified that he had signed this paper while partly stupefied by drugs and that it was signed by him while lying on the stretcher in the hallway leading to the operating room, the consent being held over his head by an orderly. He also gave the remarkable testimony that without his glasses he was not able to read and at the time of the signing of the consent he did not have his glasses with him. This amazing and untrue testimony was emphatically denied by the reception clerk in the hospital who had witnessed the signature and who testified that it was signed in the reception room of the hospital when the plaintiff first arrived there.

The Appellate Division in a scathing opinion branded the plaintiff's story as untrue and held that the surgeon was

fully justified in everything that he did. In the opinion the court said

"The plaintiff says that he went to the hospital to be operated upon for the umbilical hernia and a hernia on the right side, that he had no hernia on the left side, but that if he did have such a hernia, the doctor had no right to operate upon it, without his consent

"The plaintiff admitted that Dr G, examined his right side and his left side and also examined him for an umbilical hernia, that the doctor asked if he had pain on the left side, that he told the doctor he had no pain there. Regarding the umbilical hernia, there is no dispute, it being conceded by the plaintiff that he had such a hernia and no claim is made that Dr G was guilty of any malpractice in operating thereon

"While the plaintiff at first denied that anything was said about the left side, on cross examination he was forced to admit that fact

"Dr G testified that on June 12, 1931, the day before the operation, he met the plaintiff at the B Hospital and after obtaining his history made a very thorough examination of his abdomen. He says he found him suffering from an umbilical hernia and a direct inguinal hernia on the left side, that this latter condition was dangerous and required immediate attention. He also found symptoms of a slight indirect oblique inguinal hernia on the plaintiff's right side, but was of the opinion that plaintiff's trouble on the right side was due to adhesions which could be relieved in the course of the operation on the umbilical hernia. He said

'I asked him what he complained of. He said Pain in the belly.' He said he had been told that he had trouble with his navel and in the right groin

"In examining his abdomen I found that he had a protrusion at the side of his navel

"He had tenderness extending along the right side of his abdomen of his belly. On the right side he had symptoms of a small incomplete, indirect, oblique inguinal hernia. On the left side he had a direct hernia. The direct hernia on the left side permitted the introduction of the fingers directly into the peritoneal cavity in contradistinction to the one on the right side

"The doctor testified that the condition on the left side could not be discovered by looking at it and could not be ascertained except by introducing the finger, and that upon tugging upon the abdominal wall the patient complained of pain and a tender

area. The examination disclosed that the plaintiff was suffering not only from an umbilical hernia which everyone agreed upon, but from a hernia on both the right and left sides; the one on the left side being dangerous and requiring immediate operation for the reason that a direct hernia is potentially more dangerous than an indirect hernia. It was at this time that Dr. G. told the patient about the left hernia. . . .

"Dr. H., the doctor who had examined the plaintiff . . . and sent him to the hospital for the operation by Dr. G., assisted Dr. G. and saw the direct hernia on the plaintiff's left side when it was pointed out to him by Dr. G. He testified:

'Q. Now, in the meantime, after Dr. G. stopped his work on the umbilicus, did you observe what next step he took so far as the left inguinal hernia was concerned? A. He started ahead on the left inguinal and when he got it open, then he called my attention to the hernia that was there.

'Q. When you get it open, is there hernia—is the hernia something that you can see? A. See and feel. You can put your finger on it.

'Q. Of course, you can tell by the sense of feeling before it is ever opened, but after it is opened up, what is there to see? What do you see and what do you feel? A. You see a bulging, a pouch, a bulging.

'Q. That was there, was it? A. That was there, yes.

'Q. That was something you could see and there was no question about it? A. No question about it.

'Q. Did he call it to your attention? Of course, you were working on the same abdominal wall and did you see it or don't you recall? A. I saw the hernia. . . .

"We have therefore the uncontradicted testimony of the two doctors who operated on the plaintiff and who were in the best position to know the plaintiff's condition; that the plaintiff was suffering from a direct inguinal hernia on the left side which was a serious menace not only to the plaintiff's health, but in the event of strangulation, a danger to his life and the extent of which could be fully discovered only during the operation to the umbilical hernia.

"There seems to be no doubt but that under such circumstances the doctor was not only justified but within his rights in performing the operation on the hernia on the left side.

"No set rule can be laid down with reference to the method to be used by a doctor in operating. When a doctor makes a diagnosis and during an operation is confronted with a situation requiring the exercise of his judgment, especially in a

case of this kind where the doctor first operated on the umbilical hernia and then established the necessity to operate upon the hernia on the left side, he should not be held liable when it is not shown that he improperly exercised his judgment or that he failed to use the ordinary degree of skill. The fact that Dr. G. was not anxious to operate is borne out by his refusal to operate on the right side because he thought it unnecessary at that time and that the condition might clear up without an operation."

The court branded as untrue the plaintiff's claim with respect to the manner and respect in which the consent to the operation was signed. It said:

"In the present case, he made a thorough examination and diagnosis and decided the nature of the operation necessary to aid the patient, who consented in writing thereto. The circumstances surrounding the signing of the consent as well as the physical facts, are strong evidence that the plaintiff was not testifying to the truth in this case. When confronted with his written consent for the operation he testified in effect that he did not know what he was signing; that he was without his glasses and could not read; and that it was signed while he was lying on a stretcher being carried into the operating room; that an orderly held the consent over his head, also holding a board in that position against which board the consent was resting and that he signed the consent with a pen and ink in that manner without reading it and while under the influence of a drug.

"An examination of plaintiff's signature to the consent shows that it is legibly written, exactly on the line provided for signatures, and shows no evidence of having been written under such difficulties, nor any evidence that plaintiff was under the influence of a drug. Anyone who can sign his name as clearly and legibly and on such a straight line as plaintiff did, could not have been under the influence of a drug, and must have been conscious of what he was doing. The writing upon the straight line does not indicate that the plaintiff required glasses to find the line or its location, and would indicate also that the plaintiff must have had his glasses if it be true that he could not see to write without them. Furthermore, the signature was witnessed by Miss J., the reception clerk in the hospital. She testified that she

was at present parish secretary in St J Church and that when this paper was signed she was registrar and admitting officer at B Hospital, that the paper was signed in the admitting office of the hospital on the main floor, and that plaintiff was perfectly conscious at the time, that she never was inside of the operating room and did not know which floor it was on, that the office was on the 'ground floor in the main entrance hall as you come in the door,' and that is where the paper was signed. It is wholly improbable that if the paper had been signed in the place and under the conditions testified to by plaintiff, Miss J's signature would have been on it when her work was wholly confined to the first floor."

The court disposed of the liability of the corporate defendants by reference to the adjudicated cases on the subject under consideration and said

"In *Laubheim v DeKoninglyke Nede Landache Stoomboot Maatschappij* (107 N Y 228), the Court said

"If by law or by choice the defendant was bound to provide a surgeon for its ships, its duty to the passengers was to select a reasonably competent man for that office and it is liable only for a neglect of that duty (*Chapman v Erie R Co*, 55 N Y 579 *McDonald v Hospital 120 Mass 432* *Secord v St Paul R R Co*, 18 Fed. Rep 221). It is responsible solely for its own negligence and not for that of the surgeon employed. In performing such duty it is bound only to the exercise of reasonable care and diligence and it is not compelled to select and employ the highest skill and longest experience

"Dr G was an experienced surgeon and was shown to be exceptionally able. He had operated many times upon patients for hernia and was constantly in attendance at leading hospitals. When the insured and the insurance carrier employed such a well qualified doctor, their duties ceased. They were not liable for anything that occurred thereafter."

It is a sad commentary on the jury's system that the jury could have given any credence to this unfounded claim, but equally gratifying that the Appellate Division not only reversed a judgment obtained by the plaintiff but did so with an opinion which branded the plaintiff's story as false and untrue. This case illustrates the necessity of a written consent prior to the operation. True it is that the plaintiff sought to circumvent the written consent and succeeded before the jury in so doing, but when the case went to the Appellate

Division this written consent was of great importance and was a vital factor in causing the Appellate Division to reverse the judgment below. Had it simply been a question of the surgeon's word against the patient's there would have been nothing before the Appellate Division to demonstrate, as we were able to do in this case, the falsity of the plaintiff's testimony

Negligence Claimed in Performing Tonsillectomy

A young man consulted a specialist in nose and throat work regarding the condition of his tonsils. The doctor examined him and found that his tonsils were filled with pus and diseased. He put the man in the operating chair in his office, injected novocaine around the tonsils and with a dissector and a snare removed both tonsils. There was very little bleeding.

The doctor had the patient remain in his office for about nine hours resting from the operation, and then he sent the man home. He gave the patient instructions to notify him in the event that any untoward developments took place and to return in about a week.

The next the doctor heard from the patient was the third night after the operation. Then he got a telephone message that the patient was bleeding. He requested that the patient come to his office, explaining that he could better treat the patient there than at the patient's home. The patient insisted that he could not travel such a distance, and the doctor made arrangements for the patient's family physician to attend him. He later learned that the family physician called at the patient's house and found that the patient had been taken to some other doctor. It was claimed that the doctor to whom the patient was taken found that part of the tonsil on the left side was still present, and that said remaining portion was the cause of the hemorrhage.

The patient instituted a suit against the first doctor charging him with alleged malpractice and, particularly making the charge that the defendant failed to remove the entire tonsils and that a blood vessel was scraped. The case came on for trial and just as it was about to be reached, the plaintiff's attorneys apparently realizing that they were unable to prove a cause of action against the doctor agreed to discontinue the entire matter.

Plastic Surgery on Nose

A young woman consulted a doctor specializing in nose and throat work and plastic surgery and gave him a history of having five years before undergone a nasal plastic operation. The bridge of her nose was broad and unshapely and she requested the doctor to undertake to correct the said condition. She entered a hospital. The doctor undertook the operation putting her under local anesthesia. He made a transverse incision along and within the nose at the inferior edge of the upper lateral cartilage at the conjunction of the cartilage of the septum. He then elevated the skin and periosteum. He made another incision at the extreme lower end of the pyriformis opening on both sides and freed the periosteum from the bone. The freed portion of bone he bent toward the median line. He applied a lead splint which held the bone in position.

The doctor saw her daily at the hospital for six days and each day he removed the splint, inspected the nose and replaced it and found that her condition was satisfactory.

She made a considerable number of visits to the doctor's office after she left the hospital and when he discharged her, her nose was shapely and showed a marked improvement in appearance, but she complained that it was not as she had anticipated.

She brought a law suit against the doctor in which she claimed that the doctor had entered into an agreement with her whereby he contracted to improve the appearance of the plaintiff's nose without any resulting facial scars or disfigurement. She claimed that the defendant breached his agreement in that he failed to properly change the shape of her nose, and further that he failed to remove a certain scar. Defendant denied that any such agreement had been entered into.

The case came on for trial before a judge sitting without a jury, and at the close of all the testimony, the Court directed a verdict in favor of the defendant thereby finding that the doctor had not breached any agreement entered into with his patient.

Treatment of Laceration of Thigh

A boy twelve years old was brought into the office of a general practitioner for treatment with respect to a severe laceration

of the outer aspect of the thigh. The doctor was told that the laceration was received by the boy while he was riding on a sleigh and his leg was torn by a piece of wood. The doctor found a comparatively clean open wound about five inches long, which penetrated all four layers of skin. The doctor searched for foreign bodies and found none and painted the entire area of the wound with iodine, and the skin around the wound with the same substance. The doctor sutured the wound with two interrupted sutures of silkworm gut and then repainted the entire area with iodine and applied a wet dressing. The boy returned the next day and the wound seemed to be in good condition. The doctor again painted the wound with iodine and applied another dressing. On the third day the boy again returned to the doctor's office and there was a slight infection present. The stitches were thereupon opened and the skin was washed off with Dakins' solution and a wet dressing and a bandage applied. The patient was told to keep the wound moist by application of the said solution every three hours. The following day the infection was still present and was treated in like manner. Six days after the original injury the wound was apparently healing very well and wet dressings were discontinued. No more pus was present and dry dressings were applied after the wound had been painted with a weak solution of iodine. The patient was told to return for further treatment, but the doctor never saw him again.

A malpractice action was instituted against the doctor in which it was claimed on behalf of the infant plaintiff that the defendant doctor had failed to properly treat the injury to the plaintiff's leg in that he permitted foreign substances and dirt to remain in the wound and caused the child to suffer from blood poisoning. It was further claimed that as a result of the defendant's negligence that the child had partially lost the power of locomotion in the leg. The case was reached for trial and was directed to proceed to trial in one of the trial terms as a jury case, but instead of proceeding with the trial of the action the plaintiff's attorney being unable to convince the defendant's counsel that there was any merit to the action consented to discontinue the same, apparently knowing that he had no case against the doctor.

PHYSICAL THERAPY IN A HEALTH RESORT

WALTER S. McCLELLAN, M.D.

From the Medical Department of the State Reservation Saratoga Springs

When one considers physical therapy in a health resort, one finds two striking differences from the usual practice. First, hydrotherapy forms the keystone of the work, and second, the opportunity to build up a desire for health by attention to both the physical comfort and the mental relaxation, is to be emphasized.

During the season of 1933, there were given at the State reservation baths, 109,429 treatments. The distribution of these treatments is presented in Table I.

TABLE I—NATURE OF TREATMENTS GIVEN AT THE STATE RESERVATION BATHS, SARATOGA SPRINGS, 1933

1 Mineral water baths	89 456
2 Massage (general and local)	7 732
3 Eliminating treatments (electric cabinet salt rub and douches)	7 137
4 Colonic irrigations	2 602
5 Local heat treatments (infra red or hot pack)	1 749
6 Miscellaneous	753
Total	109 429

The natural carbonated mineral water bath which makes up the large proportion of our work is prepared from the water of the Lincoln springs. In Chart I is presented a graphic picture of the constituents found in the Saratoga waters.

In using the natural carbonated mineral water for balneotherapy, there are certain controllable factors which may be varied to produce different effects in a course of treatment. Usually the temperature is kept near the indifferent point of 92° to 95° F. In the treatment of circulatory disorders and nervous conditions where a toning-up process is desired, the temperature may be lowered gradually to 86° or 88° F. If the purpose of the treatment is the application of heat, as in many forms of rheumatic conditions associated with pain, the temperature of the baths may be increased to 98° or 100° F. The temperature must be regulated for each individual case as is found suitable in his particular condition. The duration is generally 8 to

15 minutes, starting with the shorter time in the bath and gradually increasing to a longer interval. In some patients this period may be extended to 20 minutes in order to produce relaxation and relief from pain. The frequency of the baths depends again on the condition of the patient and they are usually given four or five times a week for a period of about four weeks. In giving the treatments, an experienced attendant prepares the bath according to the prescription, and observes the reaction of the patient. In general, the rest period of one half to one hour follows the bath. In addition, many patients are directed to return to their room and rest there for another hour.

A canvass of 1,000 patients was made during the past season to determine, if possible, what physical disorders were present in the patients who came to Saratoga for treatment. A registration card was prepared so that the complaints of the patients interviewed could be recorded. These cards were filled out by the house physicians during an interview with the patient and when the history was not clear-cut, a physical examination was made.

A summary of the information obtained from this canvass is presented in Table II.

TABLE II

Primary Complaint	No of patients
1 Heart and circulatory disorders	293
2 Rheumatic conditions	267
3 Functional nervous disorders	130
4 Gastro intestinal conditions	128
5 Metabolic diseases	26
6 Miscellaneous diseases	57
7 No disease	99
Total	1 000

Among the factors which account for this distribution are (1) the stress which has been placed on the importance and value of the natural carbonated mineral water bath in the treatment of circulatory disorders, (2) the desire of the arthritic patient to seek every possible aid in at-

tempting to relieve his condition; (3) the lack of a well-organized program of treatment for these chronic diseases; and (4) the desire to keep well as evidenced by the number who come for general tonic treatment who have no definite physical ailment.

With the information presented in this survey, it is necessary to consider the nature and type of physical therapeutic procedures which are of value in each of these groups as well as to determine the indications and contra-indications in relation to the application of the special type of treatment available in the particular health resort.

HEART AND CIRCULATORY DISORDERS

Attention has been drawn to the importance of physical therapeutic results in the treatment of cardiac conditions. Groedel¹ reviewed the information on this subject in his book which deals particularly with the indications and importance of the carbonated mineral water bath in circulatory disorders. More recently the author³ has summarized the information available regarding the influence of the natural carbonated mineral water bath on the physiology and clinical picture in circulatory disorders. A series of natural mineral water baths, properly prescribed, produces definite and beneficial changes in the physiological activity of the circulatory system. During the course of the bath a definite hyperemia appears, showing that there is a very marked filling of the capillaries of the skin. This is associated with an increased minute volume output of the heart, usually a slight reduction in pulse rate, and consequently more efficient action of the heart itself. In many patients who suffer with stenocardial pain, relief may be experienced during and after the series of baths. The influence of the baths on the blood pressure is variable, depending entirely on the etiological background

for the blood pressure. In patients where a nervous factor plays a distinct part in the elevation of the blood pressure, definite and sustained reductions of the pressure result from this type of treatment.

In association with the use of the mineral water bath, properly regulated exercise, preferably an active form, such as walking, not too strenuous golf, and the like, play an important part in building up reserve. The use of general massage and of various types of mechanical exercising apparatus have their place in keeping up the general physical condition of the patient, even though the cardiac condition will not permit vigorous active exercise.

Treatment of this nature in a health resort seems particularly beneficial in patients with moderately diminished myocardial reserve, mild angina pectoris, and functional cardiac disorders. It is obvious to the thoughtful physician that he can expect to make no change in the damaged valve in rheumatic heart disease or in the sclerosed vessels of advanced coronary disease. In these conditions, benefit may be obtained by improvement in the functional activity of the heart muscle. Observation of patients in the health resort where natural carbonated mineral waters are found indicates that patients with advanced decompensation, severe luetic heart disease, marked cardiac asthma, or any patient with acute endocarditis or pericarditis with fever should not be sent to the health resort. In other words, any patient who requires bed care can best be treated at home, and when the cardiac condition improves, he may be sent to the health resort for a course of treatment.

RHEUMATIC CONDITIONS

It is probable that this group has received the most attention from the standpoint of treatment with different forms of physical therapy. Diseases of joints, conditions affecting the nerves or muscles, in fact, any painful conditions associated with the system of locomotion have been included in this group. It is not the author's purpose to subdivide this group more specifically, but to consider the place of physical therapy in this large group of patients.

Recently Lautman² has discussed the place of hydrotherapy in arthritis. He points out that hydrotherapy produces the beneficial effect by its thermal influences resulting in vasodilatation, relief of pain, elevation of temperature, sweating, and diuresis, and by its physical properties

which permit the supportive treatment of affected joints in general, or allow the counter-irritative effect to be produced in the form of sprays and douches. It is evident that the beneficial influence of physical therapy whether applied in the form of hydrotherapy or local heat application as packs, infra-red light, or diathermy will produce its beneficial effect either by improved elimination or by a better circulation, local and general, or by both. The physician must realize that, with the inactivity associated with the painful condition either in nerve, muscle, or joint, the patient becomes less active and in severe cases quickly takes to his bed with the result that both elimination and circulation, which depend in a large measure on the activity of the individual, are seriously impaired.

One great object in the treatment of these conditions is the relief of pain, as that is a very prominent factor in many of them. As the pain is relieved, then attention is turned to improving the function of the damaged part so that it may take up its normal activity again. Toward this goal, namely, the relief of pain, local applications of heat have been used for generations. Reference is made here to the more or less chronic conditions because it has been shown in acute exudative disturbances of joint or bursa that cold is more beneficial than heat because the latter tends to increase the amount of exudation and thus may definitely aggravate the pain. However, by far the largest majority of patients in this group who come to the health resort for treatment are of the chronic type so various measures for the local application of heat are used extensively. These include the hot mineral water pack, radiant-heat cabinets, infra-red lamp, and others.

In a health resort it is customary to combine this form of local treatment with a general program of baths or some form of eliminating treatment. If the patient who is suffering from this disorder is obese and full-blooded, then the eliminating treatment consisting of electric cabinet, salt rub, and douches produces beneficial results. This treatment in combination with properly regulated diet aids in the reduction of weight with the consequent mechanical relief of affected joints. In the wasted, anemic, debilitated individual, such as is found not infrequently with rheumatoid arthritis, the general treatment must be applied with great care. Here the warmer mineral water baths seem to exert a definite

beneficial effect, particularly when associated with some form of local treatment following. It must be stressed at this point that the use of any physical measure in a health resort or in any other place should be correlated with a general treatment of the patient as a whole and properly graduated to fit the patient's tolerance. It accomplishes no very beneficial result to apply diathermy to a local painful joint and pay no attention to the severe secondary anemia which so frequently is associated with rheumatoid arthritis. This fact has been very aptly stressed by Minot⁵ in his presidential address before the American Clinical and Climatological Association. He states that the physician who directs the treatment of a patient with arthritis must consider the proper balance between rest, exercise, diet, removal of infection, drug and vaccine therapy, and physical measures. He considers that by far the best results are obtained when attention is given in detail to all angles of the program and he concludes that to teach the art of courageous living is often the chief prescription for the patient with chronic arthritis.

Earlier in this section, the statement has been made that the beneficial results obtained in this group of patients seem to depend in a large measure on improved elimination and improved circulation. The use of the treatments available in a health resort are of distinct aid to elimination. The internal use of the different mineral waters directly results in better elimination through the intestinal tract and kidney. The proper application of the mineral water bath, with its resulting peripheral hyperemia and the general eliminating treatment with its marked sweating definitely improve elimination through the skin. In the use of the mineral water bath with its beneficial influence on the general circulation and in the local application of some form of heat therapy which produces its beneficial effect through improving local circulation about the affected joint, we have a combination which gives us the possibility of definite improvement in the circulation of these patients.

FUNCTIONAL NERVOUS DISORDERS

In this large group of conditions which may be primary or associated with some other physical ailment, the opportunity of treatment in a health resort with the proper atmosphere for mental relaxation is very great. No effort is made to treat patients with definite psychosis. In the treatment

of the borderline group, particularly those which have a diagnosis of psychoneurosis, physical therapy has been recognized for a long time as of a distinct value. Its importance was stressed by Weir Mitchell in his famous system of treatment.

The application of the natural carbonated mineral water bath with the proper use of the electric cabinet, massage and Scotch douche is distinctly beneficial in producing relaxation and in restoring this important group of patients to good health. Also, one should stress very strongly the importance of a sympathetic but firm medical direction for these patients. They need sympathy, but perhaps even more they need a strict guide to aid in the reestablishment of their self-confidence. A carefully regulated program such as can be provided in a health resort is of distinct value in the treatment of this important group.

GASTRO-INTESTINAL CONDITIONS

The spa treatment of gastro-intestinal conditions, including functional disturbances of the stomach and intestinal tract as well as various disorders of the liver and gallbladder has been based primarily on the internal use of mineral water. The place of hydrotherapy in the treatment of diseases of the liver and gallbladder has recently been reviewed by the author.⁴ The therapy recommended in these conditions includes, in addition to this internal use of the water suited to their particular ailment, the accessory use of many forms of physical therapy. The internal use of the carbonated saline alkaline waters is not advisable in any patient with a hemorrhagic condition in the stomach or intestinal tract. The relaxing effect of the mineral water bath and the application of heat in the form of hot mud packs, hot mineral water packs, mustard plasters, or diathermy over the region of the liver, have received wide attention in hepatic and gallbladder disorders. A reducing program in which dietary restriction must always stand in the first place, and in which various sweating pro-

thermic exercises play an important part, and exercises play an important part in the treatment of the place in the treatment of the heart, usually under conditions. There is a group of diseases a who suffer with stenosis, an ideal location for the may be experienced during forms of suitable series of baths. The influence on the blood pressure is varied, depending entirely on the etiological factors tried out in

this country, more and more stress is being laid on the idea that it is better to keep well and live a healthy life than it is to attempt to relieve physical ailments after they have developed. Certainly the health resort, particularly with the possibility of a proper medical health examination and of acquiring proper health habits, has a distinct and important field in this large program. When the sojourn in the health resort is carried out as part of one's semi-annual or annual vacation, it does not over-emphasize the tendency to worry regarding one's physical condition, for the stress here is placed on the importance of proper care of one's body, the place of exercise, the value of proper diet, and the possibility for the correction of minor physical conditions before they reach the stage where they will produce a definite disability. The great importance of this part of the work is perhaps best emphasized in the title which has been assigned to this discussion, with stress on the "health resort." There is not time to detail the place of the individual physical agencies in carrying out this large program, but each contributes its part to the goal.

PRACTICAL PROBLEMS

Certain problems arise in the application of physical therapeutic measures to the treatment of patients in a health resort. One must recognize that in large measure, this work is seasonal. Patients turn to the health resort in large numbers during the summer months making it difficult to keep a well-trained staff to provide the treatments. It is possible to employ attendants for only a few months of the entire year. We are particularly fortunate, however, that the peak of our load comes during the summer months when trained attendants working in the large centers of population find their work at its low point and therefore are willing to come for two or three months in the summer. Another of the difficulties arising in this type of work is the inability to follow the course of treatment to its conclusion such as is possible in the medical center where the patient is being treated sometimes for long periods. It is possible that the same patient may return to the health resort year after year, and individual physicians have found that in this way they were able to evaluate the effects of this therapy in a better way than was possible in the usual three or four weeks' sojourn.

In addition it is difficult at times to maintain an effective medical control of the

patients visiting a health resort. The mere fact that they are away on vacation gives them a certain sense of freedom and they may violate the carefully laid out program of their home physician, possibly in taking more exercise than their circulatory condition may justify, possibly indulging more liberally in food than is good for their condition, and in other ways. Many patients come requesting treatment who object to the medical examination which is recommended in connection with a course of treatment in a health resort.

These problems are being considered in formulating the general medical policy at Saratoga. With proper instruction, the patients will recognize the importance of medical regulation in order to obtain the best results from their treatments.

The home physician may aid very materially in meeting these problems. When he refers a patient to the health resort, he may advise him that it is important to be under proper medical control and he may send a resumé of the patient's record for the physician in the health resort. In return, the physician at the resort shall send to the home physician a report of the treatment. Then if the home physician will send a review of subsequent examinations throughout the year to the physician in the resort, the latter can much better evaluate the result of the spa treatment.

CONCLUSION

It has, of course, in this short time been possible to present only a brief survey of physical therapy in a health resort. The author has attempted to stress the importance of such treatment in the care of chronic conditions which affect various systems of the body, as well as the great value of a periodic course of treatment under proper conditions for healthy people. Stress should be laid on the point that treatment of this nature must be considered only in association with other forms of treatment suitable to the condition. Recognition by many physicians in this country of the importance of physical measures in the care and treatment of chronic conditions and in the public health program, has been slow.

The success of the health resort in filling a need in this country depends in large measure on the recognition that this form of treatment may accomplish favorable results in certain chronic diseases. In the last analysis, the result of any medical program is judged by whether or not the

patient is relieved of the conditions for which he seeks treatment.

In dealing with the various chronic conditions which have been discussed in this paper, it is needless to say that in many of them a return to complete health is impossible, but, if a program as has been outlined above can contribute to the relief of the condition, making life more worth living for the patient afflicted, then it will have justified its existence beyond measure.

DR. JOHN DEP. CURRANCE. I am particularly anxious to stress Dr. McClellan's point that all of these resort patients should be under proper medical supervision throughout the course of their treatment. It is regrettable that so many physicians have observed poor results in patients who had gone to one of our American spas and undergone a course of treatment without such medical advice and control. Hydrotherapy is a powerful therapeutic weapon capable of producing effects from a single treatment more spectacular than the action of most drugs which physicians employ. It is capable of producing great benefits but it is also capable of producing detrimental effects. To allow patients to take a course of hydrotherapeutic treatments without proper medical supervision is in my opinion, comparable to counter prescribing at a drug store. It is the duty of those men who are using hydrotherapy to do more research in this field, to educate physicians who are not acquainted with the physiologic effect of various forms of hydrotherapy with them and to form a conclusive battery of laboratory data which will scientifically prove the value of hydrotherapy in the various conditions in which it is employed.

The health resort has barely scratched the surface in the field of the rheumatic affections. The patient suffering from tuberculosis has been educated to realize that he should expect to be placed in a tuberculosis sanatorium for a period of months or even years. The patient with chronic arthritis should be educated to realize that the health resort which can help him so much in a short period of 3 or 4 weeks could do a great deal more if persistent effort were made in his behalf. The chronic arthritic should be made to realize also that, although hydrotherapy is one of the most valuable agents in arthritic treatment unless he is under proper medical control where hydrotherapy is not the sole therapeutic agent employed the results expected will usually be unsatisfactory.

THE PERSONALITY MAKE-UP OF THE CRIMINAL

V. C. BRANHAM, M.D.

Deputy Commissioner of Correction, New York State

The highly publicized criminal and his fictional counterpart of the screen and magazine have done much to throw a romantic aura about the subject of crime. The activities of the Dillinger type and the former power of Al Capone have aroused in many instances the imagination of the casual observers of the criminal scene. Such an observer is inclined to adopt one of two mental attitudes, either of which is an identification of the criminal with himself. Through the activities of the notorious criminal, he may receive vicariously those thrills he does not find in his own humdrum life. Or he may derive a certain amount of the satisfaction of self-castigation through the enjoyment of the severe punishment of the offender. Consequently any estimate of the make-up of the personality of the criminal must take into account the concept of the average man of the street on the subject. It is one of the major purposes of the present paper to indicate the fallacy of dealing with the problem of crime through any attitude of sentimentality toward the criminal or a craving for his severe punishment. Enlightened penologists and psychiatrists are gradually coming to the viewpoint of the adoption of a middle course which recognizes the criminal to be a man very much like the average man of the community but hampered with certain handicaps, mental, physical, and social that tend to push him over the borderline between social and antisocial conduct.

In an analysis of the criminal make up it will be advantageous to dispose of certain types of offenders with a brief discussion only. Two types are obviously irresponsible and therefore cannot be held accountable for their misdeeds. I refer to the insane and to the feeble-minded criminals, respectively.

CASE 1.—L.Z., a female of foreign birth, developed a strong attachment to her landlord and annoyed him constantly by her attentions. His friend advised that she be brought before a magistrate who warned her and dismissed the case. Her attention next turned to the friend for whom she developed an intense hatred. This was fanned by her observing him walk past the house coming and going from work. She next waylaid him on the street calling him obscene names using threatening gestures toward him. Finally

she shot him twice with almost fatal results. She was adjudged insane by the court and remanded to the State Hospital to await the return of sanity so she could be put on trial. In the hospital her manner was abusive, and she wrote threatening letters to public officials for not securing her release. She exhibited well-developed ideas of persecution, such that she was being held and tortured in the hospital at the request of the officials. Was untidy. Wrote in an incoherent manner and at times her speech disconnected.

Diagnosis: Psychosis—paranoid condition.

CASE 2.—G.C., a white male, aged 19 years, broke into a store and stole 7 bottles of beer. Psychological tests showed he had a mental level of 8 years and an I.Q. of 53. Rather nervous as a child. Teething, walking, and talking accomplished very late. He began to drink at the age of 17 years, and associated with bad company. A negligible school record and unable to hold down a job. Very easily led, and it was this factor that got him into trouble.

Diagnosis: Feeble-minded. Delinquent — Transferred to the institution at Napanoch.

The point to be noted in reference to the insane criminal is that with a slightly different set of factors present at the time of his act, he may never have committed a crime but would have been sent to a civil hospital for the insane. By the same token many inmates of civil State hospitals at the time they were committed for asocial conduct of some kind, might easily have become criminal had the circumstances been just right.

The feeble-minded delinquent differs from the prison type of offender, in being feeble-minded, more highly suggestible, more timid, oversensitive, and seclusive. He is given to the less vicious type of offenses if we except crimes of incest, rape, and arson. He shows poor memory, a lack of an adequate fund of general knowledge, less ability to concentrate on given tasks and to form associations when concentrating. His muscular movements are awkward and incoordinated, and therefore he has to seek unskilled jobs in rural communities. All feeble-minded criminals do not perform criminal acts because of their feeble-mindedness. Mental deficiency is likely to become a factor in the criminal act only when the degree of intelligence is quite low or there is unusual susceptibility to suggestion.

Another type of offender can be dismissed briefly as not belonging to the pres-

ent discussion, namely, the accidental or casual offender.

CASE 3.—M.T., white, male, a contractor and builder and holding public office with 40 years of respectable standing in his community, appropriated nearly ten thousand dollars in small amounts from the public funds. He had been experiencing financial difficulties during the period of depression and was put to it to meet the demands of creditors.

CASE 4.—In Washington, D. C., a World War veteran shot and killed his wife and turned the gun upon himself. A button deflected the course of the bullet so he suffered only a slight arm injury. The wife was 22 years of age and her husband 43. She had been estranged from him for several months and had been running a boarding house. On the afternoon of the shooting he called at the house to try to get his wife to return to him. She refused and he shot her. She wanted diversion and lively times which he did not care for nor could afford. This has been his only arrest.

CASE 5.—J.R., white, male, Italian, age 25. Became infuriated because his landlord advised his wife to have him arrested following an argument over a bag of flour. In revenge, he tossed a lighted cigarette into a pile of waste paper in the basement and set the house on fire. No previous arrests have been recorded.

In these cases the crime is an isolated event in the life of the individual. It often arises suddenly as an outburst of passion or through desperation over trying to raise money on a margin call to save securities. Some abnormal element enters into the situation, but the individual has never offended previously nor is he likely to offend again.

With the dismissal of the casual offender and the irresponsible criminal from our discussion we can refer now to the high class criminal operators who seldom come into contact with the law. One of the greatest fallacies made by many criminologists is the assumption of the premise that prison and jail records tell the story of crime. What shall we say of the blackmailers, gamblers, swindlers, fraudulent dealers, and those operating just within the law and seldom apprehended? We have little knowledge of these as individual types nor of the extent of their depredations. Criminal statistics are highly vitiated as documents of fact on the crime situation because of lack of facts on the group of criminals making the largest hauls. One makes the this group as a w largely by the craving for money and power. Poverty, compulsions, desperate circumstances, disordered mentality, and the host of factors to be noted in the lives of other

criminal types have no bearing here. This type of crime is a simple business proposition undertaken by men who are for the most part normal, shrewd and calculating individuals, often operating as a well-organized group.

A large share of the population of prisons, however, is composed of normal individuals with a somewhat different interpretation of "normality." They cannot be called insane, neurotic, nor psychopathic. The accidental and casual offender has already been mentioned. The present reference, however, is to the type that gets into trouble readily and frequently, yet one that seems to have a degree of common sense and apparently no mental abnormalities. The first subtype of this group to be discussed is the show-off. To this group belong the stick-up men, hijackers, bank robbers, and gang leaders. Such a felon is egotistical to the point that a reputation among his kind is to be sought even to the sacrifice of his own life. The criminal recently executed at Sing Sing Prison and known as Two-Gun Crowley found complete satisfaction in the front page publicity attendant upon his standing off by gun fire, for a brief period, a large detachment of New York City police. His place was assured in the minds of the underworld. He spent his last days before execution with a good deal of cheerfulness. In an exaggerated form the aggressiveness of this subgroup is seen in the bold, hazardous, and often reckless maneuver of the Dillinger type. More often, however, the type lacks aggressiveness and real leadership and relies on self-assurance and confidence to meet the situations that arise. To this group belong the confidence men, the swindler, the fraudulent impersonator, and bucket shop operator. This criminal type often possesses a bumptious presumption that he is a bit "slicker" than his fellow men.

CASE 6.—H.L., white, male, age 24. Was arrested by the State Police following a minor automobile accident. On questioning the man, the trooper noticed his resemblance to a bogus check passer wanted in several cities. He was placed under arrest, and further investigation of his past history showed that he had been in the habit of impersonating the sons of nationally known men, such as Booth Tarkington, Jr., Franklin D. Roosevelt, Jr., and others. His assurance and suavity had enabled him to pass the checks without any difficulty, but it was a minor offense of another nature that brought him to justice.

Almost without exception the show-off

group has an overweening vanity that leads to boastfulness when the cue should be silence, and extravagance in expenditure and conduct to impress associates he is a "big shot." It has been said that Gerald Chapman, the million dollar mail robber, would each night regularly take a \$1,000 bond, cash it, and spend the proceeds on Broadway. The psychiatric mechanism back of the show-off type is overcompensation for a sense of inferiority.

A second subgroup to the so-called normals in prisons is the inadequate personality type. Such offenders have a firm and lasting aversion to steady employment, although they may work on a criminal job feverishly for 48 hours at a stretch. As an individual he is unable to stand the monotonous grind of office or mill routine. He would rather live from day to day with no thought of the future other than the desire for the occasional opportunity of extravagant expenditure attendant upon some criminal act. Usually there is an intense selfishness that recognizes the feelings of no one but himself. His every activity is directed toward satisfying his needs alone. A lack of the sense of honor is common with this type. He is loyal to his fellow criminals only through the fear of gang reprisals. There is not a police system in the world that does not take full advantage of this fact, for it could not operate with complete efficiency without the use of the "stool pigeon."

Somewhat less of a menace but more numerous than the foregoing inadequate types is a certain class of misdemeanor wanderers. The incidence of psychopathy usually of a paranoid nature and the tendency to drug and to alcohol addiction run high in this group. Their main characteristic, however, is pronounced inadequacy. The men drift from place to place over the entire country, usually as hoboos, but often as itinerant workmen. Mechanics and other craftsmen of a sort, they obtain work fairly easily wherever they go, but they quit the job on the first opportunity. Usually the desire to see new cities or any other trivial excuse gives them the urge to move on. There are times, however, when they run short of cash and cannot find employment. At such times they turn to petty thievery.

CASE 7.—White, male, age 32 years. Born and raised in Corning, New York. Became an expert glass blower in the Corning Glass Works. Never married, but spent much of his

time in speakeasies and pool halls. Was discharged because he was irregular in coming to work and had to be sent home several times because intoxicated on the job. Made one or two ineffectual attempts to secure employment elsewhere, then began to beg. Became a professional beggar often averaging as much as \$60 a week. When one city would be worked out for him, he would drift to another. Has been picked up for begging in most of the principal cities of the country.

The chief psychiatric mechanism in effect in this group of inadequates is the inferiority feeling which is neither overcompensated nor projected. The affective tone is frequently depressive. Schizoid types are quite prevalent among the inadequates. Delusional trends if existent are usually paranoid in character but are poorly organized. The incidence of homosexuality is relatively high.

Closely allied to the inadequate personality group are certain immature types. They cannot be classed as feeble-minded, but their intelligence is definitely retarded. Their affective life also bears distinct evidence of lack of maturity. On the physical side endocrine disorders, especially of the dysplastic type, are frequent. Fröhlich's syndrome (dystrophia adiposogenitalis) is encountered more frequently than in the general civilian population. Disturbances of the functions of the thyroid and pituitary glands are definitely above the average incidence. These immatures are referred to the prison hospitals for treatment of physical disorders more frequently than other types of inmates. Defective teeth, diseased tonsils, strabismus, anemias, and poor general physical condition are common to the group.

In recapitulation it will be noted that we have now treated the so-called normal group and its various subtypes, and the legally irresponsible groups comprising the insane and the feeble-minded. The last remaining group to be discussed is the psychopath. So much has been written on the subject of the abnormality of the criminal, that there is a tendency on the part of the laity to consider all criminals to be psychopathic. As a matter of fact, the obviously psychopathic group in prison population does not run much above 25 per cent. A survey of the New York Prison population made in 1930 places the figure at 29.5 per cent. Considerable confusion exists in the minds even of professional workers as to what constitutes a

psychopathic individual. For the purpose of the proper discussion of subtypes under this grouping, it is advisable at this point to define the psychopath in nonpsychiatric terminology. The psychopath is that individual who throughout life has had great difficulty in bringing his desires and conduct into a harmonious relationship with the demands of other individuals and of society upon him, and is subject thereby to more or less regularly recurring behavior incidents that may be considered asocial but are selfishly disregarded by the psychopathic as incurring no responsibility upon himself. Briefly, he refuses to belong and hasn't the slightest concern he is not one of us. The personality in the psychopathic group is fairly well integrated. Distinction is made between this group and those deeper mental conflicts known as the neuroses.

Foremost among the psychopaths is the emotionally unstable individual. A large proportion of the assault and homicide cases belongs to this category. Often the viciousness of the attack is entirely out of proportion to the cause that incited it.

CASE 8.—Several white men had been drinking heavily in a speakeasy in a Long Island town. One suggested going to a house of ill repute containing colored women in an isolated rural section several miles distant. Upon arrival they were met by the intoxicated negro proprietor who approached the car and tried to get the men to drive away. Finally, he lost his temper, obtained a shot gun from the house, shot one of the men, dragged his body out of the car and clubbed his head into a pulp. Crimes committed under the influence of liquor tend to be unusually brutal.

A frequent explanation of assault cases is to be found in familial relationships in which some boy in the family group develops an intense hatred toward his father or older brother.

CASE 9.—Several months ago there was released from the Institution for Defective Delinquents at Napanoch, a man who had acquired some distinction in his time as a first-class pugilist. He had fought Lew Tendler, Benny Leonard, and other important figures of the ring. The condition known as "punch drunkenness" developed and he had to give up fighting as a means of living. His generally stupid appearance and retarded intelligence as the result of the beatings he had received, prevented him from obtaining any skilled work. He took to holding up people and seemed to derive a great deal of satisfaction out of beating them up as well as robbing them. His history shows that he was raised in a small upstate New York town. His father was a heavy drinker and had the habit of beating his wife and the boy. Hatred was engendered in the boy, but he couldn't whip his father. As a relief he began beating up all

the boys in the neighborhood. One morning a local fight promoter happened to pass by when the boy was engaged in one of his street brawls. The promoter was impressed and easily persuaded the boy to enter the ring as a preliminary fighter to the main bout. His career was speedily launched. It afforded a means for taking out on others the blows he had received from his father. The matter goes a little deeper than this, of course, because the real psychological explanation is to be found in the strong attachment of the boy for his mother, the rivalry with his father, and the loss of the love object through violence.

The projection mechanism noted in this case is especially common in homicide cases. Murder usually falls into one of two categories. It may be an accidental affair or incidental to some other crime. A driver runs over a pedestrian, a man kills in self-defense or in the process of a hold-up, the robbers may be surprised and be forced to shoot. Responsibility for the act is there, of course, but premeditation is not clearly indicated. The other type of murder shows a distinct premeditation to kill. The victim in many of these cases, especially if the crime has been perpetrated with unusual brutality, becomes a surrogate for the father of the murderer. The true explanation therefore of the viciousness of the crime is to be found in a study of early family relationships.

Emotional instability may express itself in many ways other than through assaultiveness. The hypomanic activity of certain aggressive types of criminals has already been mentioned. The so-called "prison psychosis," which is merely a simple depression, is occasionally encountered among the emotionally unstable offenders. The most frequent method of its expression in the criminal group, however, is in emotional episodes lasting from a few hours to three or four weeks. Many criminals become highly irritable and assaultive during these upsets and may keep everyone awake by pounding on the cell doors and shouting and cursing throughout the night. Segregation is usually required. Hallucinations are rather rare during these upsets, but strong paranoid ideas are the rule. It is not rare for attempts at suicide to be made. Such episodes can be classified as being closely allied to the manic-depressive group of mental disorders, but commitment to a State Hospital is seldom necessary and the inmate appears to be entirely normal between attacks. Attacks may occur only once or twice a year, but there is a decided "rhythmically recurring" element present.

The schizoid types deserve to be listed as a subgroup of the main classification of psychopaths. The splitting off of the personality characteristic of this group accomplishes a twofold result that handicaps the individual from successful adjustment in the community. The split-off portion becomes organized into a constellation, usually paranoid in character, that may lead to definitely antisocial conduct, and the original portion of the personality becomes impoverished thereby and to a degree inadequate to meet the demands of everyday life. Schizoid reactions are common, of course, in noncriminal groups, but if other factors are operating to push an individual over the line between right and wrong, the splitting of the personality is a great help.

Lack of time prevents any discussion other than reference to most interesting psychopathological states encountered in certain types of criminals. Prominent among these are acts with unconscious motivations usually compulsive in nature such as exhibitionism, rape, and some types of theft. The early history in such cases commonly reveals frustrations in childhood that are highly emotionalized and frequently take on a sexual coloring. Thus the theft may represent a love object of which the offender was deprived in early childhood. Deserving of mention are cer-

tain types of epilepsy or its equivalents, especially when the criminal act has been perpetrated during a state of amnesia or manic furor. The escape mechanisms involved in drug and alcohol addiction are worthy of notice. Anxiety states are frequent factors in antisocial conduct. The criminal act is an expression of repressed material arising from mental conflict. In the criminal type repressions are more likely to take the form of overt acts than fantasy formation. In other types of criminal psychopathology, however, especially where schizoid trends are present, the entire personality becomes involved in the antisocial conduct, and free fantasy formation occurs. Such individuals are relatively common in the community but seldom come to the notice of the police because the fantasy formation tends to nullify action. When an overt act is performed by such an individual, however, it tends to be bizarre and atrocious. The Leopold-Loeb affair is a case in point.

In conclusion, may I call attention to the fact that no attempt has been made in this paper to offer any suggestions as to treatment of the criminal nor prevention for crime. The prime object has been to indicate a few of the many types of antisocial conduct with brief reference to underlying causations.

A TRIP TO THE WOODSHED

The vices of modern youth are blamed by some on the neglect of what Professor William James called "Dr. Spankster's Medicine." It is a fact, anyway, that the boys smoked fewer cigarettes in the days when the fathers used to march them out to the woodshed now and then. "Willie," said father, "if you saved the money you spend for cigarettes, you could pay for a college education." A similar kindly spirit breathes through an editorial in the bulletin of one of our County Medical Societies out East New York way. "Are you a member of your County Medical Society?" it asks. "Its dues are not prohibitive. Eight cents a day could readily be spared by the average physician. The cost of one pack of cigarettes a day will cover your dues for that day, and at the end of the year you will have some money left over."

If you are a member, the writer continues, are you attending meetings and are you getting on the floor to voice your sentiments about the various matters under discussion? Or are you one of those who prefer to let others do the "dirty work" while you are playing bridge, and subsequently sulk because things are not done the way you would like to have them done.

You are a doctor and people come to you to help them with their problems. At the

present moment you are confronted with serious problems. Face them and try to solve them. You cannot do that alone. You must join the group. If you fail to join us and work with us, the lot of medical men will be as bad as that of the decent and honorable Germans under Hitlerism. The County Medical Society is offering you the opportunity to use the well established machinery to express yourself and to fight for your rights and privileges. Become an active worker in the Society. Your word is as good as that of its President. Do not sulk; do not day dream; do not complain in the staff room of your hospitals; it will get you nowhere. If you do not like the way things are done in the Society, come down to its meetings, offer constructive criticism, and help to better things. Take interest in your County Medical Society. Attend its meetings and participate in its activities, and you will be a man and a doctor rather than a slave or servant to some politician.

The Director of the new Institute of Experimental Medicine, to be constructed in Moscow, is Professor Fedoroff. The staff will number 3,500 persons, including scientists in medicine and all allied sciences, engineers, hospital personnel, and unskilled workers.

THE CONTINUOUS INTRAVENOUS METHOD OF FLUID ADMINISTRATION (VENOCLYSIS) IN PEDIATRICS

SAMUEL KARELITZ, M.D.

From the Department of Pediatrics of Mt. Sinai Hospital, New York City

In 1831 Latta¹ first injected large quantities of saline solution intravenously into adult patients suffering with cholera. The idea occurred to him after reading O'Shaunessey's² report in which he called attention to the loss of water and salt from the blood of patients suffering from this condition, and suggested replacement therapy. Latta, like O'Shaunessey, felt that blood dilution and replenishment of water and salt were necessary and that he could best accomplish these by intravenous saline injections. His results were good, but often were inadequate because of the return of the collapsed state a few hours after the injection was given. Evident as it was that continuous intravenous injection of fluid was indicated, this procedure did not come into use until sixty-five years later, in 1896, when Cox³ recommended it in the treatment of cholera.

In 1910, Thompson,⁴ one of Cox's associates, reported his experience with continuous intravenous therapy in cholera for the period between 1896 and 1910. Soon thereafter this procedure was recommended for other conditions by Friedmann,⁵ Matas,⁶ and others. They and Woodyatt,⁷ Hendon,⁸ Titus,⁹ Hirshfeld,¹⁰ Hyman, and others reported their extensive experience in the laboratory and clinically in the treatment of conditions such as surgical shock, intestinal obstruction, circulatory collapse, and eclampsia. Hendon has suggested that the procedure be called "venoclysis," and Friedmann referred to it as "Dauertropfinfusion."

Except for the application of venoclysis to the treatment of toxicosis in 1929 (reported by Karelitz¹¹ in 1931) and for our report¹² of its successful application to other conditions, the literature reveals only the brief report of its application by Harris and Stoddard¹³ in 1928. There also appear Brush's¹⁴ description of a new apparatus for venoclysis (1931), more recently a confirmation of our results in alimentary toxicosis by Cohen, Miller, and Kramer,¹⁵ and the successful treatment with venoclysis of a case of accidentally induced hyperparathyroidism by Lowenburg.¹⁶

A discussion of alimentary toxicosis will best illustrate the application of venoclysis

to pediatric conditions since it is probably the best example of what Atschley¹ has called medical shock, and except for its etiology, it is clinically and chemiopathologically almost identical with Asiatic cholera.

In the treatment of alimentary toxicosis, before realimentation can be attempted, the shock-like state must be overcome, and as in cholera, the circulation must be improved, urinary secretion must be increased to enable the body to excrete its retained toxins and excess of acid substances, and tissue salt and fluid must be replenished.

To accomplish these, we felt that the continuous intravenous drip of 5 per cent glucose in normal saline or Ringer's solution might be effective. At first 100 to 250 c.c. was injected rapidly in 20 to 30 minutes, after which the flow was reduced to the rate of 100 to 200 c.c., averaging 130 c.c. per kilogram of body weight per 24 hours. This was supplemented by a blood transfusion usually given within a few hours after the venoclysis was started. The venoclysis was continued until the improvement sought was obtained, and until the child was able to take about $\frac{3}{4}$ to $\frac{3}{4}$ of its fluid requirement per ounce without ill effect on the gastro-intestinal condition. The above procedure plus a period of milk starvation for at least 36 hours and in some cases as long as 5 days, plus realimentation by frequent small feedings according to a simple milk formula increased daily for 4 to 5 days and thereafter as indicated, was carried out in over 100 cases of alimentary toxicosis.

RESULT IN TREATMENT OF ALIMENTARY TOXICOSIS

When 100 to 250 c.c. of the fluid was injected rapidly, or soon thereafter, the circulation improved as evidenced in the quality of the pulse, the elevation of the blood pressure, and the better color of the skin. The respirations changed from the hyperpnea to more normal breathing; the expression of the eyes became brighter and clearer. Restful sleep usually ensued. The improvement seemed better sustained after the blood transfusion. Diuresis became evident either promptly or within a few

hours, vomiting ceased, thirst was created almost immediately, and the diarrhea was either promptly stopped, diminished, or gradually improved. The blood dilution occurred within the first few hours of treatment as was noted by the drop in the hemoglobin and in the reduced serum protein. The azotemia usually cleared within 24 hours and the acidosis improved progressively. These infants drank water eagerly and did the same when the milk was started. The initial rise in blood pressure was temporary in some cases, but as the fluid administration continued the improvement became permanent.

The period of venoclysis varied from 9 to 256 consecutive hours, usually 36 to 72 hours. When the venoclysis was continued for longer than 36 to 48 hours, in some cases visible edema became manifest. Although this was usually not associated with ill effects, nevertheless it was coincident with a marked drop in serum proteins and was therefore a signal for the discontinuation of the venoclysis. In some instances where continuance of the venoclysis seemed necessary, a 15 per cent hypertonic glucose solution was injected to increase the urinary output, or an additional transfusion was given to increase the blood serum protein, and thereby temporarily reduce the edema. The visible edema usually cleared up spontaneously in 1 to 3 days after venoclysis was discontinued. Some of the injected fluid was retained longer as was indicated by the weight of these children.

The more marantic the infant, the lower was the drop in the serum protein and the more rapidly developed the edema. The edema occurred regardless of whether normal saline or Ringer's solution, plus 5 per cent added glucose, was used. The fluid retention was less marked, however, when 5 per cent glucose in distilled water was injected.

Few cases which came to postmortem examination revealed considerable fluid in the peritoneal cavity and edema of the tissues including the brain. In fact, one child who had received a total of 500 c.c. of fluid in the 24-hour period preceding its exitus, at postmortem examination had about 500 c.c. of fluid in the peritoneal cavity besides some edema of the viscera. Apparently the tendency to edema exists in cases of toxicosis even before therapy is started. The McLure-Aldrich¹⁸ test emphasizes this by the rapid absorption time in many of these cases before treat-

ment is started. Furthermore these infants which came to postmortem examination were the most severe cases and those usually complicated by severe infections, congenital cardiac anomalies, or birth injuries. Our results were very encouraging. Of about 100 cases of alimentary toxicosis observed the 88 more severe ones were treated in the manner previously described. Of these, there were 14 deaths, or a mortality of 15.9 per cent. It must be added that of the 88 cases, only 6 were over 12 months of age, and the majority of them were from 2 weeks to 8 months of age. In this series there were 14 marantic infants.

In the evaluation of these results we should not lose sight of the fact that the venoclysis was only the method of administering fluid, salts, and glucose in lieu of the oral, subcutaneous, or intraperitoneal routes, and that the blood transfusion, the rest, the period of oral starvation, and the realimentation by the staircase method were very important in our routine of treatment of alimentary toxicosis.

Soon after our early experience with venoclysis in the treatment of toxicosis it became apparent that the procedure might be applied to other toxemias and to severe metabolic disturbances in infancy and childhood, for regardless of the etiology, it is clear that any condition in which there is failure to imbibe sufficient water and salt, or a loss of these by vomiting, diarrhea, hyperventilation, or excessive sweating, or in the excretion of glucose, or the combination of several of the above factors will ultimately lead to a picture very similar to that of alimentary toxicosis, namely, vasomotor collapse and shock. It is well known that these are the findings in diabetic coma, intestinal obstruction, severe burns, heat exhaustion, and in severe toxemias of infection such as influenza, and some cases of septicemia, or dysentery in acute adrenal insufficiency, and histamine shock.

Up to January, 1934, a fairly representative group of such patients were treated with the aid of venoclysis.

Six cases of cyclic vomiting between 5 and 11 years of age were treated by venoclysis. Two of these cases had received 300 to 500 c.c. of 5 per cent glucose solution intravenously on one or two occasions before venoclysis was started, but the improvement was very transitory. These children relapsed into the comatose state. With one exception improvement followed

within an hour after venoclysis was started and progressed uninterruptedly. The one exception seemed to improve at first, then became worse. Marked diuresis and glycosuria were noted and it was believed that dehydration was caused by the treatment. The solution was therefore made hypotonic and a blood transfusion was given with good results. Venoclysis was given for a variable period from 6 to 24 hours in these cases.

Four cases of diabetic coma, one a child of 5 years, failed to respond to repeated injection of insulin and carbohydrates given per os, but they promptly emerged from the coma when the same amount of insulin and glucose were given by venoclysis for the greater part of a day.

A girl of 9 years was admitted with acute nephritis and uremic coma complicating cervical adenitis. She was oliguric. The few cubic centimeters of urine obtained on catheterization were red, contained much albumin, and many red blood cells. Her blood pressure was 130/90. Her blood chemistry revealed a urea nitrogen of 79 mg. per cent, CO_2 content of 73 volumes per cent and 445 mg. per cent of cholesterol. She received the venoclysis of 10 per cent glucose solution for 24 hours, during which time she voided very little urine, but on catheterization 550 c.c. of bloody urine were obtained. The blood pressure dropped to 106/86. The child looked better and made a progressive recovery. The urea nitrogen dropped to 18 mg. per cent within 36 hours.

A male infant of 3 weeks with pyuria and staphylococcus bacteremia became anuric and revealed marked urea nitrogen retention and acidosis. He looked extremely toxic. By aid of the venoclysis this child promptly began to urinate freely and looked much better, but ultimately succumbed to his infection. He had multiple widespread abscesses in his viscera including his kidneys.

Two other infants 5 and 9 months of age, respectively, one with a sacral tumor causing loss of the bladder sphincter control and cystitis, the other with chronic pyuria, became oliguric and collapsed. These children were treated by venoclysis for 5 and 10 consecutive days, respectively. The fluid dosage was similar to that in the cases of alimentary toxicosis. The clinical improvement was striking as were the findings of the blood chemistry, which were typical of uremia with acidosis before treatment was started.

Five infants with pyloric stenosis admitted in very poor condition so that operation was considered too dangerous were given venoclysis. Two of these children who had convulsions and a markedly elevated blood CO_2 and lowered sodium chloride content were treated, one for 7 days, during which time he improved sufficiently to be able to undergo a Ramstedt operation. By way of the venoclysis these infants were given the fluid and sodium chloride of which the tissues and blood were starved, and the glucose aided in maintaining them until ingested food passed the pylorus.

One child of 5 months with intussusception for 43 hours was treated by venoclysis before, during, and for 24 hours after the operation was performed to release the intussusception. A few days later vomiting of bile-stained fluid, epigastric distention, and failure to pass stool or gas by rectum resulted. Treatment by venoclysis with 5 per cent glucose solution for 3 days, gastric lavage, and oral starvation brought striking and rapid improvement clinically as well as in her blood chemical data.

Of 3 infants with widespread eczema who suddenly went into circulatory collapse and whose chemical pathology was similar to that of cases of alimentary toxicosis, 2 recovered under this treatment, whereas the third developed pneumonia and succumbed to it.

Several cases with extensive burns were given venoclysis for at least 24 hours resulting in marked diminution of the toxemia and improvement of the general condition.

Several cases of erysipelas with severe toxemia were successfully treated by venoclysis for variable periods of 2 to 7 days.

Few very young infants with widespread pneumonia and severe diarrhea and vomiting were treated by venoclysis with only temporary improvement in some cases and complete recovery in others.

Of 8 cases of streptococcus peritonitis in infants and children from 6 months to 4 years of age, 7 were only temporarily benefited by venoclysis. They looked brighter and their circulation was improved, but they ultimately died. The eighth case was in extremis when venoclysis was started. In some cases of peritonitis associated with a ruptured viscus (appendicitis), venoclysis seemed to be a life-saving measure.

The experience with several cases of tubercular, pneumococcus, and streptococcus meningitis were associated with only temporary improvement, no case having survived.

with a short bevel, usually a 21 gage, is introduced and strapped to the extremity with adhesive tape. The needle may have to be changed after 12 to 24 hours of venoclysis.

This table illustrates some of the blood chemical data before, during, and after treatment with venoclysis in the various cases mentioned in the text. Note the tendency for all figures to return to normal.

A boy of 11 years, ill with tetanus and unable to swallow, was aided tremendously by venoclysis given in interrupted periods of 12 hours during which sodium amytal was also given to cause sleep. This boy also received serum intrathecally and recovered.

Few cases of hydrocephalus associated with brain abscesses were temporarily relieved of their severe headaches and vomiting by venoclysis given in periods of 12 hours. They ultimately succumbed with diffuse purulent meningitis.

Thus, numerous disturbances in infancy and childhood were treated with the aid of venoclysis with considerable success as had been done before in comparable conditions in adult medicine and surgery.

TECHNIC

The technic of venoclysis is simple and has been described in some of our previous publications. It is worthy of repetition, however, that when working with older children whose veins are large enough for venepuncture, it is unnecessary to expose the vein surgically. A needle

FLUID REQUIREMENT

Our infants were in the majority of cases under 8 months of age, and only a few were 12 to 16 months of age. Such infants received from 100 to 200 c.c., averaging 130 c.c. per kilogram of body weight per 24 hours, or 0.4 c.c. per centimeter² of the sitting height squared per 24 hours. On the first day this quantity was increased by 25 to 50 per cent. No child of 12 months or younger needed more than 1,000 c.c. in 24 hours.

The daily quantity of fluid per kilogram of body weight diminished as the age of the child increased. Estimated roughly, children up to one year received the maximum of 1,000 c.c. in 24 hours. Those from 1 to 3 years received 1,000 to 1,800 c.c., depending on the size and ages of the children. The older children received approximately 40 to 100 c.c. per kilogram of body weight per 24 hours, depending on the amount desired.

TYPES OF FLUID USED

We have used normal saline, Ringer's, and Hartman's solution each, with 5 per

cent added glucose in all cases except where more hypertonic or hypotonic solutions were indicated. Our results do not show striking differences with these solutions. We believe that the glucose is of great value because it is a readily utilizable food and acts as a muscle stimulant, but primarily because it acts as a diuretic and an aid in the combating of acidosis. We have found that 5 per cent glucose is most ideal, because stronger solutions cause clotting and earlier clogging of the cannula and may cause diuresis to the point of dehydrating the patient.

We believe that if diuresis is established early, as was almost always the case, there need be no fear of ill effect from the injected sodium chloride. On the contrary, this salt is usually needed. This is also true in alimentary toxicosis when the acidosis is usually a chloride acidosis.

We give blood transfusions in most conditions treated. In alimentary toxicosis we have with few exceptions, used it routinely. We feel that because of its physiochemical nature, its colloid content, it remains in the circulation longer than saline solution and thus aids the circulation, besides possibly aiding as an oxygen conveyor and a detoxifying agent. We are careful not to inject blood in the presence of severe blood concentration, but find that blood dilution occurs in the first few hours after venoclysis, after which a blood transfusion is safe and helpful.

COMPLICATIONS

The complications of venoclysis are: (1) local infection and thrombosis; (2) embolism; (3) anaphylactoid reaction; and (4) edema which has already been referred to.

We have had local occlusion of veins after 10 to 96 hours in about 25 per cent of our cases, necessitating cutting down on a second vein if the first could not be cleared.

We observed local thrombophlebitis in 4 cases. In all it cleared up after application of wet dressings for 24 to 48 hours. There seemed to be a greater tendency for clot formation in the cannula when 10 per cent glucose was used than with 5 per cent. We have not found it necessary to routinely change the vein after 24 to 36 consecutive hours of venoclysis.

As for anaphylactoid reactions, when the fluid was freshly prepared to rid it of pyrogenic substances and the glassware and tubing properly cleansed so that the old blood clot, rubber powder, and excess

alkalinity is removed as recommended by Rosenthal,¹⁰ when chemically pure salts were used, and when the fluid was injected slowly, no reactions occurred. The significance of injecting at a too rapid rate has been well presented in the paper by Hirshfeld and Hyman, who have named this reaction "speed shock."

CONCLUSIONS

Between 1928 and December, 1933, we have treated 88 severe and 12 mild cases of alimentary toxicosis and about 75 other children represented by cases of ketosis and coma associated with cyclic vomiting and diabetic coma, acute hemorrhage nephritis with anuria and hypertension, chronic pyuria complicated by collapse, oliguria, marked acidosis and azotemia, an infant with intussusception in preparation for laparotomy and postoperatively for atony of the upper intestine, pyloric stenosis cases which were almost moribund and had alkalosis, several cases of collapse in infants with eczema, a case of tetanus, and several cases of erysipelas, with gratifying results. Eight cases of primary streptococcus peritonitis, few cases of purulent and tubercular meningitis, brain abscesses, and some very severe pneumonias in very young infants were likewise treated, but in these cases the improvement which usually followed the early treatment with venoclysis gave way and the final outcome was poor, except in one boy of 4 with streptococcus peritonitis and several cases of pneumonia which recovered from almost complete collapse. Even in the cases which died, the treatment was supportive and prolonged life.

The surgeons of our hospital regularly use venoclysis in severe burn cases, in preoperative collapse or dehydration, and in postoperative shock. It is also used in extensive bleeding and to aid circulation, as well as to support the blood pressure during operation.

We believe that venoclysis is superior to the subcutaneous or intraperitoneal injection of fluid in conditions such as those discussed. In no other way than by venoclysis can fluid be injected at a steady slow rate without regard for absorption, or salts or sugar injected in varied concentration, or glucose injected in maximum quantities yet within tolerance rate. It is probably the most effective method of reducing blood concentration or serum protein, of supporting blood pressure, and relieving vasomotor collapse. It is very important

that the child is resting quietly while treatment goes on, and that stimulants or blood can be introduced through the same cannula without further disturbance to the child.

We believe that venoclysis is indicated in all toxemias and accidental poisoning of infancy and childhood, in all conditions associated with extracardiac or vasomotor collapse, in severe dehydration and blood concentration, in cases of demineralization, in severe acidosis or alkalosis, in gastrointestinal disturbances such as obstruction, mechanical or functional, in all of these conditions when fluid administration by mouth is either not possible or is inadvisable. It is further indicated to cause diuresis or the opposite, hydration of the body. By injecting solutions of proper tonicity it can be used to shrink the brain or increase the flow of spinal fluid.

In brief it is a procedure associated with relatively little danger when properly administered, only partially helpful in some conditions, but life-saving in others.

1097 PARK AVENUE

LABORATORY AIDS IN DIAGNOSIS

The New York State Association of Public Health Laboratories consists of the Directors of Laboratories throughout the State of New York which are approved by the State Department of Health. The Council of this Association decided to issue a series of leaflets on laboratory aids in diagnosis; the first one which concerned undulant fever was published in the JOURNAL some months ago. Your attention is now directed to the second one as follows:

LABORATORY AIDS IN THE DIAGNOSIS OF TYPHOID AND PARATYPHOID FEVERS

The clinical course of typhoid and paratyphoid fevers varies greatly. The symptoms may approximate those of other diseases, such as influenza, undulant fever, and tuberculosis. Furthermore, a carrier of typhoid or paratyphoid bacilli cannot be detected by clinical observations alone. Thus, laboratory examinations of specimens are of great importance for confirmation of diagnosis in suspected cases and are necessary in the discovery and control of human sources of infection.

The etiological agents, *B. typhosus* and *B. paratyphosus* A and B, are discharged in the feces and sometimes in the urine of persons having the disease and in carriers. They may also be present in vomitus, especially if this contains duodenal contents, and in pathological discharges, such as pus from suppurating lesions. The infections are communicable so long as the inciting micro-organism is present.

When typhoid or paratyphoid fever is suspected, the physician is required, by special state regulations, to submit for examination to a laboratory approved, for that purpose: (1) 10 c.c. of the patient's blood or, if this is impracticable, from two to four drops of blood collected on a glass slide and allowed to dry; (2) a specimen of fluid feces and, if there is evidence of localization in the genito-urinary tract, a specimen of urine. During the first week of the disease the

submission of blood for cultural tests is recommended. Specimens of feces must also be submitted before the patient is released.

Laboratory Aids in Diagnosis

I. *The Agglutination Reaction.*—Agglutinative properties may not be demonstrated in specimens of the patient's blood before the end of the first week of illness. During the next two weeks, serological tests may be very helpful, particularly if sufficient blood has been collected so that accurate dilutions of the serum can be made and the granular and floccular agglutinative properties can be studied.

II. *Blood Cultures.*—The incitants may frequently be recovered from the blood stream during the first week of the disease. Their presence is, however, usually transitory, though occasionally they may be found four or even five weeks after the onset of the illness.

III. *Feces, Duodenal Contents, and Urine.*—Bacteriological study of the feces and urine is important to confirm definitely the diagnosis if *B. typhosus* or *B. paratyphosus* has not been isolated from the blood. For this purpose, fresh specimens are needed unless preservative is used (30 per cent glycerol in 0.6 per cent salt solution). Urine and particularly feces examinations are of special value in searching for carriers, as their blood may not give significant agglutinative reactions. Since in most typhoid carriers the focus of infection is the gallbladder, examination of duodenal contents is often more helpful than that of feces.

Epidemiology

With the more adequate safeguarding of public water supplies, the typhoid carrier has assumed greater importance. Undiscovered carriers who are food handlers or live in a district where adequate means for sewage disposal are not available, are a particular menace.

THE NEW YORK STATE ASSOCIATION OF PUBLIC HEALTH LABORATORIES

A CLINICAL STUDY OF HERPES WITH A REVIEW OF
FIFTY-EIGHT CASESALBERT R. MCFARLAND, M.D.
Rochester

Most of our knowledge of the etiology of herpes is of comparatively recent origin. It seems to have developed as a result of failure to find bacteria in such diseases as varicella, variola, and herpes. A stimulus to a study of the viruses has been afforded by the investigation of the bacteriophage phenomena by Twart¹ in 1915. He noted that in inoculating calf vaccinia on agar tubes, a watery substance developed about the cultures which destroyed the cultures themselves. This fluid could be transmitted. He considered it to be an enzyme.

D'Herelle,² in 1921, working along the same lines, considered this material to be an ultramicroscopic organism.

The connection between zoster and varicella has been repeatedly noted by numerous authors including Cipallaro,³ Booth,⁴ and Hill and Gray.⁵ Numerous instances of varicella have developed from contacts with herpes and vice versa. Therefore, it seems fairly well established that herpes is caused by some type of virus.

DIAGNOSIS

The diagnosis is usually easy to make from the clinical picture. In the simplex type, there are usually one or two small vesicular patches occurring most commonly about the mouth and cheeks, which is of sudden onset with practically no subjective symptoms except a little tingling or slight soreness on pressure. In the zoster type, we have the typical grouped vesicles along the general distribution of some nerve trunk and usually accompanied by more or less pain and tenderness in this region.

From an experimental standpoint it was apparently not possible to transfer the virus to animals until 1932. In that year, Youmans⁶ succeeded in inoculating a rabbit with the virus from a case of acute herpetic fever. Instances are also recorded of the transfer of the virus from herpetic vesicles to children, resulting in the clinical picture of chickenpox. In 1926, Netter and Urbain⁷ began to use the complement fixation test. In their series of cases, they found that 93 per cent of convalescents gave positive complement fixation tests.

Preherpetic pain is often the first symptom of the disease and may be present for several days before the skin eruption appears. This phenomenon is often a source of error in diagnosis. It has frequently been mistaken for acute appendicitis, pleurisy, obstruction of the ureter, sinus disease, and middle ear infections.

A diagnostic point which we have frequently encountered in zoster of the trunk, is a cutaneous reaction obtained by stroking the area involved. Perhaps this phenomenon has been noted before but I have been unable to find reference to it in the literature. If the herpetic lesions are already present, the skin is stroked in this area with a pencil or the finger tip and a reflex is obtained consisting of "goose pimples," in the area supplied by that particular nerve root. If the lesions are not yet present, it can be obtained by stroking the area of most intense pain. The phenomenon lasts only five or ten seconds and then subsides. This reaction can be repeatedly produced at will. The author does not know how consistent this reaction is, but has noted it on the last five or six cases of zoster, which he has observed. It may be of value in diagnosing preëruptive cases and also the area can be outlined which may later become involved with herpetic lesions.

CLINICAL MANIFESTATIONS

Many different pictures are presented under the general heading of herpetic virus infections. One of the most severe is acute herpetic fever with stomatitis, such as has been reported by Youmans⁶ and others. At the other end of the scale, we have the ordinary "cold sore," or the recurrent simplex type. According to the most common parlance, the term zoster is retained for what is commonly known as "shingles," and consists of multiple vesicular patches, with considerable pain, local discomfort, and some constitutional symptoms and usually occurring on the trunk extremities or side of the head. The latter, or ophthalmic, type often presents serious complications because of the structures involved.

Another clinical picture is that of encephalitis. This has been observed in cases

which are exposed to artificial heat treatment. In fact, it has been suggested by Glden⁸ that a possible beneficial effect from malaria treatment in syphilis is the liberation of a virus which attacks the spirochete. In these cases it would seem that the high temperature releases for activity a latent virus, which otherwise remains dormant.

Other unusual pictures enumerated by Brain⁹ are involvement of the geniculate ganglion with a loss of taste to the anterior two-thirds of the tongue with involvement of the external auditory meatus, palate, and anterior pillars, pseudo-arthritis, and motor paralysis of certain groups of muscles.

Lastly, a clinical picture which is being more frequently observed is a combination of zoster and varicella-like rash. Cipallaro³ has called attention to two such cases and the author has recently encountered a similar one, that of a lady aged 55, who had a typical group of herpetic lesions under the right shoulder with considerable pain. She also had a generalized eruption quite typical of chickenpox. She was under the impression that she had had chickenpox as a child, but upon inquiry, was unable to confirm this opinion.

PATHOLOGY

The pathology of zoster is apparently that of posterior poliomyelitis. The virus is apparently not detected in the blood or spinal fluid, but according to Youmans⁶ and others it travels along the axis neurone. The vesicles are not due to a trophic disturbance of the nerve trunk but actually contain the virus itself. In rare instances, the infection apparently travels along the nerve sheath back to the posterior roots and out again along a new nerve trunk. This may account for the appearance of lesions distant from the original site of infection.

PREDISPOSING FACTORS

Brain⁹ and others have classified herpes under "symptomatic" and "idiopathic" types. This is probably not a fundamental distinction, but the term symptomatic is used where some obvious contributing factor has given the virus an opportunity to cause trouble. In reality all types of herpes are idiopathic under this classification; that is, they are caused by a virus, and other factors which have been mentioned in the etiology are really only predisposing.

Jacobs¹⁰ has called attention to a case of bilateral herpes following the ingestion of arsenic accidentally mixed with flour. The explanation would seem to be that the arsenic intoxication predisposed the individual to the ravages of the virus. Wollheim¹¹ similarly has reported cases resulting from the administration of arsphenamine. Bismuth has occasionally been blamed with precipitating herpetic attacks. Artificial heat, exposure to wind, sunlight, and sudden changes of temperature often apparently initiate an attack.

CONTAGIOUSNESS

The author does not believe there is any evidence that herpes simplex is clinically contagious. There is, however, definite evidence, as shown by Hill and Gray,⁵ Cipallaro,³ and others, that zoster is a source of infection. Numerous cases of chickenpox have developed in children in a household where a case of zoster existed. Occasionally, but much less frequently chickenpox has been the source of an attack of herpes in another individual. It is a generally accepted fact, that children are more susceptible to the clinical manifestations of chickenpox and adults more susceptible to zoster.

IMMUNITY

Herpes simplex tends to predispose to subsequent attacks rather than to protect an individual. In fact, recurrences are the rule in this type. In this respect herpes simplex seems to differ from herpes zoster and would indicate possibly a different strain of virus. Recently, attempts have been made to immunize individuals against recurrent herpes simplex by inoculation with smallpox vaccine. The author has been informed of this procedure through verbal communication with several practitioners. The vaccination usually does not "take," but beneficial results may be obtained if it is repeated two or three times at three-week intervals. Zoster, on the other hand, seems to confer an immunity on the individual and recurrences are rare. Measures aimed at protection are therefore comparatively useless.

TREATMENT

Aside from the possible trying of smallpox vaccine as a preventive measure, very little treatment is necessary in herpes simplex for the individual attack. They usually subside in a period of about a week under some soothing local application.

In 1931, Ruggles¹² called attention to the possible value of sodium iodide to relieve the pain of zoster. Whether there is any special benefit derived from the intravenous route, the author is not certain. The work of Osborne¹³ seems to show that iodides are absorbed and eliminated very quickly regardless of the route of administration. Possibly equally large doses of iodides by mouth would be as efficacious. In a considerable number of cases it does seem to afford relief from pain. Relief can also be obtained in many cases by roentgenotherapy of the nerve trunks involved and occasionally, the author has seen good results from counterirritation such as an erythema exposure to quartz light. Locally, relief is obtained more readily by drying lotions and protection with cotton batting. This method seems to be preferable to wet dressings or ointments. More recently, Niles¹⁴ has called attention to the possible benefit of pituitrin injections.

As complications arise, the treatment will be determined by the organ or part involved.

John Gipner (personal communication) stated that glaucoma is not infrequent after ophthalmic herpes and suggests that all cases involving the eye be followed up with this in view. Impairment of hearing due to the involvement of the tympanic membrane and taste impairment of the anterior two thirds of the tongue may result from involvement of the geniculate ganglion. Cases are also reported of localized muscular paralysis as the result of involvement of a motor branch. Bram⁹ has reported cases of involvement of joints simulating arthritis. Among the less frequent complications might also be mentioned encephalitis and death of a general septic type. The author has reviewed 58 cases of herpes encountered in private practice during the last two years. Table I is self-explanatory and indicates some of the data obtained. The outstanding points which seem apparent from this short series might be emphasized. First, it is apparent that the simplex type or ordinary cold sore is the most common, has a marked tendency to recur, individual attacks are

TABLE I

Type	Types encountered, per cent	Tendency to recurrence per cent	Complications per cent	Duration	Pain per cent	Treatment	Etiology
Simplex	61	50	Glands of neck 6 Local edema 6	Average 10 days	—	Vaccine 6% Local treatment only 94%	17% Sun and wind 6% colds
Zoster	27	6	Postherpetic pain 4 Varicella 1 case	Average 3 weeks	94	Quartz light K. I. NaI and x ray, sedatives	None
Ophthalmic	12	—	Postherpetic pain 5 Corneal ulcers 25 Glaucoma 8	Average 2 months	100	Sod iodide x ray sedatives	None

COMPLICATIONS

The usual pain preceding or accompanying zoster can hardly be considered as a complication. There are, however, a small number of cases in which the pain persists for weeks or even months after the eruption subsides. This complication is often very resistant to treatment, but relief may sometimes be obtained by continuing the use of the iodides and x-ray as in the treatment of the active stage. In the ophthalmic type, severe and permanent damage to the sight may result. When one side or bridge of the nose is involved, we are very likely to have involvement of the eye also. This consists of vesicles on the cornea, which may result in permanent scars, retinal detachment, or glaucoma

of short duration, there is very little associated pain, and predisposing factors seem to be extreme changes in temperatures, sun, wind, and acute coryza. Very little treatment is needed for the individual attack, but for troublesome recurrences vaccination with smallpox virus seems to be of value.

The next most common type is zoster involving the trunk or extremities. In contrast to the simplex type, there is very little tendency to recurrence. On the contrary, an immunity seems to be established by an individual attack. The duration is longer in this type, and more or less pain is the rule. The ophthalmic type or that in which there is involvement of nerves of the tongue, ear, eye, and scalp, is the least common, but the pain is most severe.

the duration longest and complications more frequent. The last two types might be classified as strictly idiopathic, as in none of the cases studied was there any obvious predisposing cause.

Either sodium iodide intravenously or by mouth, or potassium iodide, seems to be of value in controlling the pain. Relief is also obtained by x-ray therapy of the involved nerve trunks, possibly by quartz light therapy and by the use of appropriate sedatives and local applications.

Complications of the simplex type consist of local glandular enlargement and local edema. The zoster type may be complicated by an accompanying varicella-like rash, postherpetic pain, and residual scars. The complications of the ophthalmic type are more common and severe, consisting of postherpetic pain, corneal ulcers, detached retina, and glaucoma.

SUMMARY

1. The virus nature of herpes seems to be fairly well established.
2. It would seem probable that a different species of virus is responsible for the simplex type than the ophthalmic and

zoster types. This suggestion is based on the different clinical appearance, variations in symptoms, difference in the tendency to recur, and the difference in the age group affected by each type.

3. The effect of treatment is summarized.

4. Various complications which may be encountered are enumerated.

NEW AID FOR THE PARALYZED

A new method by which paralyzed individuals can replace their lost functions by the aid of simple, inexpensive mechanical appliances, electrically activated, is described in the *New York Medical Week*.

The several contrivances are the outgrowth of experiments by Dr. James S. Doyle, a New York engineer, who, at the request of the chief surgeon of this hospital, devised the original apparatus for a fourteen-year old patient totally paralyzed from the neck down. The only portion of his body the boy could voluntarily move was his head so, by an arrangement of photo-electric cells and a couple of light beams above his bed, the boy was able, by a movement of his head to right or left, interrupting one or other of the light beams, to turn over the pages of his book,

switch a radio on or off, or the electric light, or ring for a nurse.

The present apparatus, as shown at the Reconstruction Hospital, utilizes, in addition to the photo cell control, human breath control, and bodily contact in which practically no muscular power is necessary. To operate the photo-electric cell, all that is necessary is for the patient to interrupt a path of light and, in the case of the sound control, to blow into or speak into a miniature megaphone. Energizing the mechanism by means of bodily contact was another aspect which was demonstrated by touching of a sensitive rod by the tip of the patient's tongue.

Operating a typewriter, knitting or weaving machine, setting type and other occupations are among the possibilities so that such a disabled patient may ultimately become self-supporting.

A BETTER KIND OF "MEDICINE SHOW"

Do you remember the old-time cheap wagon shows that used to tour the rural towns with flaring torches and blaring bands, selling "tonics" that were mostly cheap whiskey at a dollar a bottle? Well, Germany has produced a "medicine show" of a very different sort. It is a huge motor truck, bearing in large letters the word "Gesundheit," or "Health." It is put on the road by the enterprising Hygiene Museum, of Dresden, and accounts say that it is designed to give graphic instruction in sanitation and care of the health to dwellers in the rural districts.

The autobus carries a large tent and collapsible seats, with the help of which a small

hygiene museum, with auditorium and cinema, can be erected in a short time in the remotest villages. Its transportable electrical plant makes it possible also to illuminate its exhibits in front of the tent and inside—plastic figures, graphs, pictures, charts, preparations, etc.

This first traveling show is devoted chiefly to the prevention of accidents in agriculture and industry, and the prevention of contagious diseases. The cinema supplements the effectiveness of the various exhibits, and there is even a Punch and Judy show for combining entertainment and instruction of the children.

THE MANAGEMENT OF PLACENTA PRAEVIA

An Analysis of the End Results of 57 Personal Cases

LOUIS E. PHANEUF, M.D., Sc.D. (Hon.), F.A.C.S.

Professor of Gynecology, Tufts College Medical School, Gynecologist and Obstetrician-In-Chief, Carney Hospital, Boston

The uterus, during pregnancy and labor, is divided into two segments, the upper segment or contracting zone and the lower segment or zone of effacement and dilatation. Normally, the placenta is inserted on the anterior or posterior surface of the upper segment. Under certain abnormal conditions it may be attached to the lower segment when it is known as *placenta praevia*.

Three types of placenta praevia are recognized. *Marginal placenta praevia* exists when the placental edge is palpated, by the examining finger, at the internal os. *Lateral or partial placenta praevia* occurs when part of the cervical os is covered by the organ. *Central or total placenta praevia* is found when the os is completely covered by placental tissue. The degree of placenta praevia is influenced by the amount of dilatation of the cervix. Thus, what may be found to be a marginal placenta praevia at the onset of labor may prove to be a lateral as labor is more advanced as a good deal of the organ protrudes through the dilating os. Conversely, a placenta may appear to completely cover the os at the beginning of dilatation and may be found to do so only partially at the end of the first stage. As a result of placental implantation in the lower segment, three conditions arise: (1) increased vascularity of that region, (2) friability of the tissues leading to severe rents or tears during delivery, and (3) invasion of the cervical musculature by the villi leading to the rare pathological lesion known as placenta accreta.⁴

As a general principle, it may be stated that placenta praevia is about ten times more frequent in multiparae than in primiparae. Davis¹ gives the incidence of the disorder as 191 cases in a series of 41,686 births during a period of twelve years at the Chicago Lying-In Hospital, 0.46 per cent or less than once in 200 cases. Williams² stated in his textbook: "In general it would be approximately correct to say that it is met with about once in 1,000 cases in private, as compared with once in 250 cases in hospital practice." The incidence will depend, to a large ex-

tent, upon the accuracy with which examinations are made and statistics are collected.

Although many etiological factors are adduced, disorders of the endometrium seem to play a large rôle in the causation of the disease. Solomons and Canter,³ on the bases of clinical experience and animal experiments, believe that the cause of placenta praevia lies in a defective or deficient production of the decidua formation in the upper portion of the uterus, with a normal or sufficient amount of decidua in the lower portion of the uterus. When, therefore, the fertilized ovum, enters the uterus, it will seek the place where it can obtain the greatest amount of nourishment. Since the upper portion is deficient or poorly developed to receive the tenant it will be attracted to the greatest amount of decidua reaction—in the lower portion of the uterus. Infections and frequent pregnancies are believed to be the factors which predispose to deficient decidua formation. To avoid repetition of the disease, Solomons, in a paper read before the British Medical Association in 1929, advised a curettage of the uterus following placenta praevia before the next pregnancy and stated that in his practice there has never been a "repeat" case. In view of the foregoing, curettage may prove to be a valuable addition in the treatment of this anomaly.

Hemorrhage without pain in the last trimester of pregnancy is usually due to placenta praevia, while hemorrhage with pain is the result of the premature separation of the normally implanted placenta. While seeking the cause of hemorrhage at this stage of pregnancy, a pedunculated tumor—myoma or sarcoma—a polyp, a cervical erosion, a vaginal or cervical varix may be ruled out by their peculiar characteristics. The palpation of placental tissue partially or wholly covering the os will lead to the proper diagnosis.

TREATMENT

Emphasis must be laid upon the fact that the most important single factor in the treatment of placenta praevia is the

hospitalization of the woman. This offers no great difficulty in this time and age, when many hospitals are available and where good roads lead to them. The question of vaginal packing before removing the patient to the hospital always arises. As a general principle it is best to avoid the pack whenever possible. A tight abdominal binder together with a tight vulvar pad, suffice to control the hemorrhage in the majority of cases. The pack is dangerous because it increases the element of infection. In some cases, however, this danger is less than that occasioned by a violent hemorrhage. If the pack must be introduced, due regard to asepsis must be observed as much as possible. The pack should consist preferably of iodoform gauze and, in its absence, of plain sterile gauze. In the presence of a severe hemorrhage and in the absence of gauze the vagina may be tightly packed by several large pledgets of absorbent cotton wrung out of weak lysol solution. In any event, a tight abdominal binder is applied after the introduction of the packing material. Even in a modest home, thorough scrubbing of the vulva, lower abdomen and inner aspect of the thighs with soap and water, followed by weak lysol solution, and the draping of the field with four wet, recently boiled, towels, or, if the saving of minutes is a factor, four cleanly laundered towels, soaked in and wrung out of weak lysol solution, will give a clean field through which the tamponade may be accomplished. Vaginal tamponade, however, is only necessary in a small percentage of the patients.

In the light of our present knowledge, accouchement forcé should have no place in the treatment of placenta praevia. In the treatment of this disorder there are three distinct schools of thought: (1) those who favor purely obstetrical procedures in the majority of women so afflicted, (2) those who advocate surgical methods, as, cesarean section in one of its varieties, (3) those who try to individualize their patients and apply what, in their opinion is, everything being equal, the best form of treatment for the particular patient. The author has tried to follow the dictates of the last school. The obstetrical methods may be divided into four groups: (1) the wide rupture of the membranes, the delivery being left to nature, (2) the introduction of a metreurynter, extra- or intra-ovularly, followed by spontaneous or artificial delivery, (3) the Braxton Hicks

version, with spontaneous delivery, and (4) version and extraction or forceps extraction at full dilatation of the cervix.

Accumulating experience has taught obstetricians that the cervix and lower uterine segment, in cases of placenta praevia, are extremely friable, and that rupture of the uterus with its exceedingly high mortality may follow any attempts of delivery through the imperfectly dilated cervix. Hence, if a pelvic delivery is decided upon, this should not be attempted until the full dilatation of the cervix, a point which cannot be emphasized too frequently and too forcibly. Kellogg,² in a recent paper on the subject, implied that the badly scarred multiparous cervix is a contra-indication for delivery from below. This point must be stressed, since a laceration having its origin in such a scar may readily extend to the lower uterine segment and also because these scarred devices are inelastic and tear easily during the process of dilatation.

Which of the four obstetrical methods outlined above should be used in a given case? In the few women who cannot be moved to the hospital, the Braxton-Hicks version or metreurysis in the lateral or central varieties of placenta praevia and the wide rupture of the membranes in the marginal, will probably give the best results. Patients in the home are very seldom seen at full dilatation of the cervix so that a version and extraction or forceps delivery may be performed. It is understood, of course, that the attendant should not leave the patient from the moment treatment is instituted until the completion of the delivery. The third stage, after obstetrical intervention, should be carefully watched and the patient should be kept under observation for some time after the expulsion of the placenta. Ergot should be administered intramuscularly and posterior pituitary extract, by the same avenue or intravenously, in the severe forms, to keep the uterus well contracted. If, despite a well-contracted uterus, bleeding persists, the cervix should be inspected and lacerations giving rise to hemorrhage sutured. Uterine and vaginal tamponade, with iodoform gauze or plain sterile gauze may become necessary to control the bleeding in some instances.

Transfusion.—Blood transfusion has become so simplified in the last two decades that it is now extensively employed in the treatment of placenta praevia. The ad-

ministration of blood by the citrate method is no more difficult than the introduction of saline solution intravenously. This procedure is responsible for the saving of many maternal lives, as following its employment, treatment for placenta praevia may be carried out safely, where these same procedures would be dangerous, if not disastrous, if employed in a patient who had lost a great deal of blood.

The *surgical methods* employed in the treatment of placenta praevia are also four in number: (1) vaginal hysterotomy, (2) classical or corporeal cesarean section, (3) low or cervical cesarean section, and (4) Porro cesarean section, or cesarean section followed by hysterectomy.

Vaginal hysterotomy has found but few adherents and is seldom practiced for placenta praevia to-day. The friability of the lower uterine segment, the hemorrhage during the intervention, and the restricted field of operation make it difficult of performance, while the high fetal mortality speaks against it.

Abdominal delivery is constantly gaining adherents in the treatment of placenta praevia. Here one must choose between the classical or corporeal cesarean section and the low or cervical procedure. Those who favor placing the incision on the body of the uterus do so on the grounds that by so doing the placental site is avoided and there will be less hemorrhage during delivery. The protagonists of the cervical cesarean section find that by making the incision in the lower segment, the placental bed may be inspected after the delivery of the placenta, that bleeding areas may be sutured and hemorrhage controlled, that the method offers definite protection against infection in these anemic patients, and that the maternal mortality is lower. Recent statistics covering 376 cesarean sections performed for placenta praevia, 300 cervical and 76 corporeal, showed a maternal mortality of 4.33 per cent for the former, against 12.65 per cent for the latter. The Porro operation, or cesarean section followed by hysterectomy, is reserved for the badly infected woman and for the parturient whose uterus does not contract well after the delivery of the fetus and placenta. In the author's series of 57 placenta praeviae, he had only had recourse to it in one woman, or in 1.75 per cent of the cases. One point in technic worth mentioning in connection with this procedure is that it is far safer to ligate

the ovarian vessels in the infundibulo pelvic ligaments than close to the uterus in ecchymotic, friable tissue. Hemorrhage is far better controlled and secondary hemorrhage much better avoided by the former method, even though it entails the sacrifice of the ovaries.

In the author's hospital practice the method of delivery depends upon the dilatation of the cervix, the amount of hemorrhage and the parity of the patient.

Primiparous patients having a marginal placenta praevia are usually treated expectantly, by the wide rupture of the membranes and metruorrhea, and are delivered through the birth canal—normally, by forceps or by version and extraction. If the hemorrhage is free and if there is no cervical dilatation, the cervical cesarean section is resorted to. Lateral and central placenta praeviae are treated by the cervical cesarean section if the cervical dilatation is slight or absent and if the hemorrhage is severe, and by delivery through the birth canal if the opposite is true. Multiparous patients with a marginal or lateral placenta praevia are treated expectantly unless there is free hemorrhage, when the cervical cesarean section is performed. Central placenta praevia is usually treated by the cervical cesarean section, the only exception being when the patient is admitted with full dilatation of the cervix. The Porro operation is reserved as a method of security and safety in a rare neglected case. Thus far the author has not had recourse to the classical or corporeal cesarean section in the treatment of placenta praevia.

Paucot and Reeb³ presented a report, entitled "The Surgical Treatment of Hemorrhages by Insertion of the Placenta on the Lower Segment," before the eighth Congress of L'Association des Gynécologues et Obstétriciens de Langue Française, which was held in Paris on October 5, 6, and 7, 1933. This report is an extensive one and contains recent statistics on placenta praevia. The purely obstetrical interventions numbered 1,716 or 78.07 per cent, against 482 surgical interventions or 21.93 per cent. These statistics were obtained from twenty members of the Association, 19 European and 1 American, men who were heads of hospital services, their statistics showing hospital results rather than results of patients treated in their homes. Under obstetrical procedures were considered: (1) wide rupture of the

membranes followed by spontaneous delivery, (2) introduction of a metreurynter after rupture of the membranes or perforation of the placenta, (3) Braxton-Hicks version (without rapid extraction), (4) version and extraction or forceps at advanced dilation, and (5) the method of Delmas (of Montpelier), which consists of manual dilatation of the cervix, followed by version and extraction, under spinal anesthesia.

The maternal mortality in this series of obstetrical procedures was 7.82 per cent, the fetal mortality 51 per cent. The authors state that the fetal mortality has not varied in 20 years and varies but little in the hands of different operators. There is a marked difference, however, between the simple rupture of the membranes with a fetal mortality of 34.50 per cent, and the other technics, which all sacrifice more than 50 per cent of the children, the Braxton-Hicks version giving a fetal mortality of 83.60 per cent.

The surgical methods considered were the low or cervical cesarean section, the classical cesarean section, and the Porro cesarean section or cesarean section followed by hysterectomy.

Vaginal hysterotomy is taken up separately since it is more closely related to the obstetrical technics rather than to the surgical or abdominal procedures. The maternal mortality of this intervention is given as 15.38 per cent and for this reason it is not surprising that it is almost abandoned. For the above mentioned abdominal surgical procedures the maternal mortality was 8.42 per cent. This mortality is divided as follows: Low or cervical cesarean section, 300 cases, 13 deaths, or 4.33 per cent. Corporeal or classical cesarean section, 76 cases, 10 deaths, or 12.65 per cent. Porro or hysterectomy, 63 cases, 14 deaths, or 20.31 per cent.

If cesarean section, as a whole, gives maternal results almost identical with those of the purely obstetrical methods, the better results of abdominal delivery are credited to the low or cervical cesarean section. This intervention, which was slowly adopted by the French School, has now largely supplemented the classical operation. The results of this low operation are even more startling when it is considered that the majority of those who favor it had recourse to it only in 10 to 30 per cent of their hemorrhage cases and reserved it for their most severe ones. For the

child, the surgical treatment shows markedly improved results, since the gross fetal mortality has decreased to 22.42 per cent. Vaginal hysterotomy gives 39.13 per cent, abdominal hysterectomy, 25 per cent, Porro, frequently employed in desperate cases, where the fetus is already dead, 71.42 per cent, the corporeal or classical cesarean 16.17 per cent, and the low or cervical cesarean 11.11 per cent.

The study of the moment where the child dies confirms the salutary value of the surgical method, for, if the secondary mortality, due largely to prematurity, remains about the same as in obstetrical interventions, with figures of 9.05 per cent, the mortality during the course of the operation falls from 43.76 to 12.89 per cent.

The authors summarize their report as follows: "Hemorrhages from low insertion of the placenta do not justify the systematic employment of the surgical methods; the majority remain amenable to the wide rupture of the membranes. Outside of this intervention we must have recourse to the surgical methods. The low cesarean is then the procedure of choice, since it best safeguards the mother's life and shows itself very superior to any other treatment for the salvation of the child. Hysterectomy is a procedure of safety and of necessity to which it is occasionally indispensable to have recourse."

These results are those of well-trained obstetricians working in well-equipped maternity hospitals. Similar results cannot be obtained in the home, by those who have had less training. Miller, quoted by Williams,⁶ gives a mortality of 36 to 40 per cent for the mother under the expectant plan of treatment and of 66 per cent for the children. One of the most important factors in the treatment of placenta praevia is hospitalization of the patient.

STATISTICS

An examination of the author's personal records, from November 7, 1917, to October 17, 1933, shows that during this period of approximately sixteen years, he has treated 57 cases of placenta praevia. In this group 23 women were subjected to the obstetrical treatment or delivered through the birth canal and 34 were treated surgically or delivered abdominally. In the series of 23 patients treated obstetrically, central placenta praevia was encountered 8 times, lateral placenta praevia 8 times,

and marginal placenta praevia 7 times. The 8 patients who had central placenta praevia were delivered by version and extraction and there were 5 manual extractions of the placenta. In the class of 8 who had lateral placenta praevia, there was one set of twins and the following obstetrical procedures were employed: version and extraction, six times; low forceps, twice; breech extraction once; manual extraction of the placenta three times and metrorrhysis twice. Marginal placenta praevia was observed in 7 parturients, 4 of whom were delivered by version and extraction, 1 by high forceps and 2 by breech extraction; in addition there were 3 manual extractions of the placenta and one induction of labor by means of bougies. In the cases of central placenta praevia, gestation had reached seven months in 3, seven to eight months in 1, eight months in 1, and term in 3 women. In the patients who had lateral placenta praevia, gestation had reached seven months in 5 and term in 3 women. In the parturients with marginal placenta praevia, gestation had reached seven and one-half months in 1, eight months in 2, and term in 4 women. There were, then, in this series of cases, 13 premature or immature infants.

OBSTETRICAL TREATMENT OF PLACENTA PRAEVIA

Results

- 23 Cases 2 maternal deaths, or 8.6 per cent
One death caused from ruptured uterus,
the other from general peritonitis
- 24 Children born, one set of twins, sixteen fetal
deaths, or 66.6 per cent
- One patient seven months pregnant, admitted
with general peritonitis from acute gangrenous
appendicitis with rupture and who died from
general peritonitis deduced leaves—one maternal
death in 22 cases or 4.5 per cent

Thirty-four patients were treated surgically or delivered abdominally. In this series, central placenta praevia was encountered 21 times, lateral placenta praevia 6 times, and marginal placenta praevia 7 times. In the group of 21 central placenta praevia cases, 4 cervical cesarean sections with a vertical incision, 14 cervical cesarean sections with a transverse incision, 2 Veit-Fromme-Hirst cesarean sections (peritoneal exclusion), and 1 Porro cesarean section, or cesarean section followed by hysterectomy, were performed. The 6 women with lateral placenta praevia and the 7 with marginal placenta praevia were delivered by the cervical cesarean section with a transverse incision. In the 21

patients who had central placenta praevia and who were treated surgically, gestation had progressed to seven and one half months in 3, eight months in 3, eight months and one week in 1, eight and one-half months in 1, and to term in 13 women. In the 6 parturients with lateral placenta praevia treated surgically, gestation had reached eight months in 2, eight months and one week in 1, and term in 3 women. In the 7 who were surgically treated for marginal placenta praevia, gestation had reached eight and one half months in 2 and term in 5 women. Among those treated surgically, 13 premature or immature infants were found, the same number which was found in the obstetrically treated parturients.

PREVIOUS CERVICAL CESAREAN SECTION

In 5 women previous cervical cesarean sections had been done. In this class a central, 2 lateral and 2 marginal placenta praeviae were found. Two women had had two previous cervical cesarean sections and, at the time of the third cervical cesarean section, each had a lateral placenta praevia. One woman had had three previous cervical cesarean sections and, while doing the fourth cervical cesarean section, a marginal placenta praevia was encountered.

MORBIDITY

In the group of 33 cervical cesarean sections performed for placenta praevia the following postoperative complications were observed:

Septic abdominal incision	1
Separation of abdominal incision	1
Intestinal paresis, responding to treatment	1
Lochiometra. Acute gastric dilatation	1
Severe secondary anemia requiring transfusion	1
Phlebitis	2
Total	7

All mothers who had these complications recovered.

SURGICAL TREATMENT OF PLACENTA PRAEVIA

Results

- 34 Cases 1 maternal death, or 2.9 per cent
One maternal death from acute dilatation
of the stomach and intestinal paresis
forty eight hours after delivery. Patient
had had a previous operation for pelvic
inflammation. A jejunostomy was per-
formed and no sign of peritonitis noted
- 35 Infants born one set of twins 6 fetal deaths,
or 17.1 per cent

PLACENTA PRAEVIA COMPARATIVE MORTALITY

Obstetrical Treatment

23 Cases, 24 children delivered	
Maternal mortality	
Gross	8.6 per cent

Corrected 4.5 per cent
Fetal mortality 66.6 per cent

Surgical Treatment

34 Cases; 35 children delivered

Maternal mortality:

Gross 2.9 per cent
Fetal mortality 17.1 per cent

The fetal mortality in each instance is uncorrected and includes the macerated fetuses, the stillborn and the premature infants.

In the cesarean group all babies delivered at or near term survived.

CONCLUSIONS

1. Placenta praevia is one of the grave obstetrical complications.

2. Improvement in the mortality statistics of this malady will depend largely on the hospitalization of the patients whenever possible.

3. The treatment may be obstetrical or surgical. Each case should be individualized and the best form of treatment for the particular patient applied.

4. Accouchement forcé has no place in the modern treatment of placenta praevia.

5. Blood transfusion plays an important rôle in saving maternal lives.

6. Abdominal cesarean section, preferably the low or cervical operation, gives the best results for the central and lateral varieties.

7. Obstetrical procedures should receive first consideration in the marginal variety

and in the lateral type in multiparous patients.

8. In nulliparous women, before the onset of labor, and when the hemorrhage is severe, cesarean section will give the best results regardless of the variety.

9. Fetal results are markedly improved by abdominal delivery.

10. Hysterectomy is rarely necessary, but, in the presence of uncontrollable hemorrhage, it becomes an operation of necessity and safety.

11. Fifty-seven personal cases of placenta praevia are reported. For the obstetrical procedures, the gross maternal mortality was 8.6 per cent, the corrected maternal mortality 4.5 per cent, while the uncorrected fetal mortality was 66.6 per cent. For the surgical methods, the uncorrected maternal mortality was 2.9 per cent and the uncorrected fetal mortality was 17.1 per cent.

12. The fetal mortality was due, in a large measure, to prematurity.

VITAMIN CLAIMS IN FOOD ADVERTISING

The Committee on Foods of the American Medical Association has published a criticism of indefinite or general vitamin claims in advertising, which, it says, are vague, noninformative and misleading and do not permit a distinction between foods as sources of respective vitamins. Vitamin claims, the committee rules, shall stipulate the specific vitamin or vitamins present. Vitamins present in a food in insufficient quantity to contribute in any significant manner to the respective vitamin values of the diet do not warrant mention. It is desirable that warranted vitamin claims be expressed in appropriate terms indicative of the relative potency of the food as a source of the vitamins in the dietary schedule. Foods may be considered relatively as fair, good, and excellent or rich sources of vitamins. Statements of vitamin unitage in numerical quantities per gram (and per ounce if desired), where established, are to be encouraged on container labels and in advertising. The type of unit used should be specified. These statements shall be so expressed as not to be misleading.

Relative distribution of the vitamins in the various foods is presented in tables by Sherman (Chemistry of Food and Nutrition, fourth edition 1932), by Rose (Foundations of Nutrition,

revised edition, 1933) and by a committee appointed jointly by the Lister Institute and the Medical Research Council of England (Vitamins: A Survey of Present Knowledge, 1932). These tables should serve as a guide for comparative vitamin claims for food in advertising.

A new plan to provide purer milk in England had been devised by the Milk Marketing Board, a body appointed by the government to control the milk industry. It is to come into operation in October. As described by the London correspondent of the A.M.A. Journal, it is proposed to prescribe a standard of purity for milk, and producers who conform to it will receive a bonus on every gallon of milk. Funds for the payment of this bonus will be provided by the levy of a small sum on all producers of milk. The new grade will be termed "accredited milk." The farm, the cow and the milk will be subject to expert examination by local health authorities. The object is not to produce a highly superior grade of milk of limited quantity but to raise the general standard of milk. It is thought that the majority of producers, attracted by the bonus, will conform to the prescribed standard of purity.

EPILEPSY OF ALLERGIC ORIGIN

T WOOD CLARKE, M D

Utica

To the average physician, the term allergy means asthma, hay fever, eczema and urticaria, and nothing more

Recent investigations, however, prove that the phenomena of allergy may involve practically any organ in the body

Pollen dermatitides are well known Chronic rhinorrhea, or perennial hay fever, may be due to foods or to animal emanations such as dog hair or parrot feathers Recurrent bronchitis has been traced to canary feathers or cat hair Many cases of croup are manifestations of allergy

Gastro intestinal allergy may appear as canker sores, cyclic vomiting, and acute or chronic digestive disturbances Cases of scleritis, vernal conjunctivitis, retinal edema, and episcleritis have been assigned an allergic etiology

Certain acute and chronic arthritides appear to have an allergic basis¹

The manifestations of allergy which we are considering to day, are those of the central nervous system, especially epilepsy

When a specific protein comes in contact with a body cell previously sensitized thereto, an allergic reaction occurs This manifests itself by three processes stimulation of gland secretion, spasm of smooth muscles, and hyperpermeability of capillary walls causing local edema² If these pathological changes take place in the bronchi, bronchitis or asthma results, if in the nasal mucous membrane, hay fever or rhinorrhea appears, if in the skin, eczema, urticaria, or angioneurotic edema makes its appearance, and if in the intestines, acute edema of the intestinal wall, causing symptoms resembling appendicitis, abdominal tumor, intestinal obstruction, or mucous colitis, may occur

Theoretically, if a process resembling angioneurotic edema should occur in the cranial cavity involving the meninges, the brain substance, or the pituitary gland, the sudden increase of intracranial pressure should produce transient symptoms analogous to those of brain tumor The classical symptoms of brain tumor are headache, dizziness, vomiting, symptoms referable to pressure on the optic nerve, and convulsions The first four of these are characteristic of an attack of migraine When

the convulsions occur alone, and supposedly idiopathically, we call it epilepsy

Where patients have died during an attack of migraine, the pathologist has found nothing but cerebral edema If death occurs from status epilepticus, a similar picture presents itself

Asthma, urticaria, migraine, and epilepsy all have a familial tendency all occur suddenly and periodically, the attacks are of brief duration, and between the violent outbursts the patient is usually in normal health All are characterized by local edema, all, until recently, were considered of unknown etiology and usually incurable These facts alone should arouse our suspicions that they are but different manifestations of a common underlying pathological process

In 1919, Pagniez³ in France called attention to the similarity between migraine and the allergic diseases, treated a series of cases of migraine with nonspecific proteins and peptones, and got good results

In 1921, Thomas R Brown,⁴ in a study of migraine, called attention to the fact that one group of cases seemed closely related to protein ingestion

In 1927, Vaughn⁵ performed skin tests on 33 cases of migraine, removed from the diet all proteins giving a reaction, and, in many cases, stopped the headaches He then fed the offending proteins, and produced prompt attacks of typical migraine In 16 cases he believed allergy to be definitely proven and found that the attacks could be prevented or produced at will, 10 cases were not benefited, of 7 he lost track Vaughn believed the condition to be one of angiospasm

In 1928, Balyeat⁶ in a study of the heredity of the allergic diseases, found that they followed closely the Mendelian law, and that migraine was interchangeable with asthma, hay fever, and urticaria in the linkage

Since this, Balyeat⁷ has published several studies of migraine, and in 1931 had collected 202 cases In practically every case a positive skin test to some food was obtained A family history of allergic disease was discovered in 82 per cent of the cases, and 81 per cent of the patients

themselves, suffered from some other manifestation of allergy. He concluded that all cases of migraine are of allergic origin, but he differed from Vaughan in his belief that the lesion was a cerebral edema, not an angiospasm.

In 1930, Rowe⁸ reported 86 cases of migraine, 74 per cent gave a family history of allergy, 12 per cent of the patients had asthma, 17 per cent hay fever, 43 per cent cutaneous allergy, and 64 per cent abdominal symptoms which he considered of allergic nature.

In 1931, Eyermann⁹ reported 63 cases of headache. In 44 of them, not only were positive skin tests to various foods obtained, but the headaches could be prevented and produced at will by feeding the foods to which the tests proved the patient sensitive.

In Eyermann's cases other symptoms suggesting allergy accompanied the headaches, such as coryza, dizziness, nausea and vomiting, edema of eye, nose, lips, and slight general edema of the skin. This last was so definite that some of the patients increased 5 lb. in weight during the migraine attack, to lose it again as soon as the attack was over.

Eyermann advises the term allergic headache rather than migraine, and believes that it is due to a cerebral edema resembling an angioneurotic edema.

In 1932, De Gowin¹⁰ confirmed the work of Balyeat, Rowe, and Eyermann in a study of 60 cases of migraine. In the same year, Goltman,¹¹ in a study of 43 cases, concluded that foods are of paramount importance in the majority of cases, but that occasional inhalants as animal hair, pollens, orris root, and insect powders are causative factors. He believed that combinations of allergic and endocrine migraine are common.

It will thus be seen that the evidence that at least some cases of migraine are of allergic origin and are curable, rests on a firm theoretical, experimental, and clinical basis.

The close affiliation between migraine and epilepsy has long been recognized.¹² A study of the two conditions from the allergic viewpoint adds fresh evidence to this relationship.

Among the many causes mentioned as inciting attacks of epilepsy, indiscretion in diet has always held a prominent place. In 1921, Wechsler¹³ called especial atten-

tion to the relations of foods to epilepsy and said that it seemed to him "that there is something akin to a sensitization, a reaction of the organism to certain proteins, or possibly endotoxins, which result in convulsive phenomena." He quoted one patient in whom his epileptic seizures were cured by removing eggs from his diet.

In the same year Thomson,¹⁴ of London, in a study of 200 cases of infantile convulsions, stated his belief that these were usually cases of poisoning by milk, eggs, or cereals.

In 1922, Ward¹⁵ propounded the theory that epilepsy was as much a manifestation of allergy as is asthma, and he reported two typical cases of epilepsy, one sensitive to milk, cheese, casein; beef, and veal, entirely relieved by removing these bovine foods from the diet, and the second relieved by the removal of cows' milk and its products.

In 1923, Howell,¹⁶ of Columbus, reported a series of 14 epileptics, who showed sensitivity to either foods or bacterins. On numerous occasions epileptic attacks were precipitated within a few hours after ingestion of foods to which the patient reacted, and the complete withdrawal of these from the diet, or in the bacterial cases, vaccine inoculations, caused marked improvement in the epilepsy.

The first extensive study of epilepsy from the allergic viewpoint was made by Wallis and Nicol¹⁷ in London, in 1923. They studied 122 insane epileptics. Each case was given skin tests by the scratch method with the following group of proteins: (1) egg proteins, (2) meat and fish proteins from beef, mutton, veal, chicken, game, fish, shell fish, etc., (3) milk from various animals, (4) vegetable proteins including nuts and fruits, (5) cereals, (6) peptones, and (7) control of sodium hydrate. Of the 122 cases, 46 gave positive skin reactions. In a series of 100 controls who were not epileptic, only 4 reacted. The authors also reported 14 epileptics in whom positive skin tests were obtained, who were cured, either by withdrawing the offending proteins, or by giving peptone.

In 1924, Miller¹⁸ pointed out many points of similarity between asthma, urticaria, migraine, and epilepsy. He showed that all had a hereditary character and a nervous element, were modified by acute infections and by pregnancy, and have

been reported cured by the injection of various nonspecific proteins, such as horse serum, tuberculin, typhoid vaccine, and peptones

Van Leeuwen and Zeydner¹⁹ isolated a substance from the blood of cases of asthma, urticaria, migraine and epilepsy, which, when injected into animals, produced muscle contractions. No such substance could be isolated from normal patients or sufferers from other ailments.

Duke,²⁰ in his book, refers to a patient with convulsions, asthma, temporary paralysis, and anesthesia who gave skin reactions to various vegetables and fruits. She was free from symptoms as long as she avoided the offending proteins. Attacks could be produced by feeding the specific allergens.

In 1927, an extensive and suggestive piece of work was carried out by Ward and Patterson.²¹ One thousand epileptics at Craig Colony and the New Jersey State Village for Epileptics were given skin tests with protein extracts. The authors fail to state how many tests were made on each patient, or just what type of reaction they considered to be positive. Of the 1,000 cases, however, 48 per cent gave one or more positive reactions, while in a series of 100 nonepileptic controls only 8 per cent reacted. Apparently these most interesting findings were not followed up as no report of therapeutic results has appeared.

In 1927, Spangler²² analyzed 100 cases of epilepsy, and found that in 88 per cent of the cases there was a family history of allergy. He then reported a series in which the ingestion of certain foods was believed to be the exciting cause of the epileptic attacks, and the withdrawal of the foods caused their disappearance.

Rowe,²³ in 1927, reported 2 cases of epilepsy in children, one associated with asthma in which pollen treatment cured both the asthma and the epilepsy, and the other in which horse hair desensitization resulted in freedom from attacks.

In 1930, Waldbott²⁴ reported 2 cases of epilepsy and asthma alternating.

Levin,²⁵ in 1931, reported a child of three who had convulsions, gave skin reactions to cheese, was free from convulsions on a cheese-free diet, but had a return on breaking her regime. He also referred to a case sensitive to cat hair, that was free from convulsions after removal of cats from his environment.

In the same year Spangler²⁶ reviewed the present theories of epilepsy and allergy and concluded that certain experimental, hereditary, biochemical, chemical, and therapeutic factors support the theory that epilepsy is a response to an allergic metabolic disturbance.

During the past three years, several other authors²⁷ have reported series of cases in which there was evidence that the epilepsy was of allergic origin.

The writer's personal experience with the allergic factors in epilepsy, while not sufficiently extensive to be conclusive, is significant enough to bear reporting in the hope of stimulating others to further investigations of the subject.

Of the cases in private practice, as some patients did not return to have the tests completed, and others have been lost track of, statistics are of no value. However, there are two cases which have been observed from one to three years.

CASE 1—M F, 10 years of age, was referred to the author by Dr. Price Lewis of Holland Patent, N. Y., with a diagnosis of epilepsy. Her family history is not significant. Her father and mother are in good health. Her father is a dairy farmer and she lives on the farm. In her past history, the only point of importance is that she had asthma since infancy. The onset of her epileptic convulsions was at the age of six years. The epileptic attacks had increased in frequency during the past four years, until they were occurring on an average of twice a week. Though unfamiliar at that time with the work that had been done on the relation between allergy and epilepsy, it was suggested that if the asthma could be cured the epileptic attacks might become less frequent. No hopes were offered for a cure of the epilepsy. The parents agreed, and eighty skin tests were made by the scratch method with the following positive results: cattle hair +++, cottonseed +++, radish ++, and cheese+.

Cotton was removed from her environment, radishes, cheese, and salad oils eliminated from her diet and, as her home conditions precluded the avoidance of the hair and dander of cattle, weekly inoculations of cattle hair extract were begun on May 19, 1931, with a dose of 0.1 cc. of a 1:100,000 dilution. These were continued weekly with increasing doses, the last dose, 0.9 cc. of a dilution of 1:500 being given eight months later, on January 22, 1932.

The results were surprising. As the dose of cattle hair increased, not only were the asthmatic attacks relieved, but the epileptic seizures became less and less frequent, and in November, 1931, ceased entirely. Since then the child has been quite well, and has had neither attacks of asthma nor epileptic convulsions.

CASE 2—B W, born in 1916. An only child. Cesarean birth. Nursed 4 months, then given cows' milk and dextrimaltose. At the age of eighteen months she had facial eczema. She

refused to eat eggs. She had numerous colds and stomach upsets. She had frequent attacks of croup. At 5 years, she had pneumonia. Since she was three years of age, she has had hay fever every fall, sometimes followed by asthma. She had ragweed injections at 10 years of age with some improvement. At that time skin tests showed her sensitive to spinach, onions, rice, and corn.

Since she was 4 years of age she has had digestive upsets, constipation, and recurrent attacks of mucous colitis requiring weekly irrigations. At 11 she was given a set of gastrointestinal x-rays. The roentgenologist stated that she had "a spot on her spine." Though she had no spinal symptoms, she was put in braces and was under the care of Dr. Goldthwait for 4 months.

Her epileptic attacks date from the age of 10 years. During the succeeding nine years, she has had convulsions varying from once a month to once every three months. They always occurred in bed. She has fallen out of bed and bitten her tongue. The patient was a chronic invalid.

Owing to the extensive allergic history, 186 skin tests were made by the scratch method with the following results: 4+ to goldenrod, 3+ to banana and asparagus, 2+ to giant and short ragweed, dahlia, dandelion, cabbage, corn, garlic, onion and potato, and 1+ to orris root, pyrethrum, tobacco, coffee, buckwheat, beet, and the pollen of mugwort and sunflower. Suspicious, but not definitely positive reactions were given to tea, barley, flaxseed, oats, grapefruit, rhubarb, spinach, and almond.

A rigid diet was ordered and on March 4, 1933, inoculations with giant and short ragweed, goldenrod, and dandelion were started and continued until August.

The result has been that the patient, last summer had the first autumn without hay fever in fifteen years, and is much improved in regard to her intestinal condition. The only convulsion she has had in the past fourteen months was last autumn when, after driving for two days on her return from her summer home in Rhode Island and eating at restaurants where her dietary régime was probably somewhat lax, she had one mild attack. She says that for the first time in her life, she considers herself to be well.

The author has recently been given the opportunity to investigate the allergic status of the epileptic cases at the Utica and the Marcy State Hospitals. This study has only just begun and will be reported in full later. In passing, however, it is of interest to note that of the first 10 cases studied, one patient gave four 2+ and one 1+ reactions. One gave twenty 1+ reactions, one gave three 1+ reactions, 2 gave two 1+ reactions, and one gave one 1+ reaction. These all gave variable numbers of +, —, or suspicious reactions. Of the three who did not give definitely positive reactions, one gave one that was suspicious. The other two were quite negative. Each case was given scratch tests with 164

allergens. Thus, in this brief series of psychopathic epileptics, it will be seen that 70 per cent gave evidence of allergic susceptibility.

From a review of the literature and from personal experience, the author believes that there is evidence of a close relation between allergy and not only migraine, but epilepsy as well.

Theoretically an acute allergic edema of the brain can explain all the symptoms of the two diseases.

Cases of epilepsy, as well as migraine, give a disproportionately large percentage of positive skin reactions, showing their hypersensitivity to certain foods or environmental influences.

In many cases the attacks have ceased when the offending proteins have been removed, and in some have been made to recur by returning these to the diet or environment. Desensitization by specific protein inoculations has been followed by complete recovery.

While epilepsy may also be caused by various pathological conditions as trauma, arteriosclerosis, or endocrine disfunctions, there is sufficient evidence that some of the cases are of allergic origin to warrant a careful study of the food and other idiosyncrasies of every case of epilepsy.

It is well within the range of possibility that a study of the allergic idiosyncrasies of cases of infantile convulsions, and the regulation of the diet in accordance therewith may, in certain cases, prevent the onset of epilepsy in later years.

Where an epileptic patient gives a family history of allergy, or shows some other allergic manifestations himself, such a study is especially indicated.

If such studies can relieve but a small percentage of the unhappy sufferers from this tragic affliction, the time devoted to making the investigations will be indeed well spent.

SUPERSTITION DIES HARD

It would seem well-nigh incredible if it were not related first hand by the editor of the *Mental Hygiene News*, published in Utica. An earnest visitor, it appears, called at the office of the State Department of Mental Hygiene and wished to take an insane patient with him, accompanied by a doctor and two attendants, for two or three hours. After some discussion, his method was disclosed. The patient was to be tied to an evergreen tree, his hair and nails were to be cut off, a cavity was to be made in the tree and the hair and nails inserted and sealed away from bees, bugs, etc. Cure was to come forthwith. The visitor said it was an experiment, which he had never tried, although he got the directions from a very old book, older than the Bible.

A colleague tells of a similar kind of "hair magic." An old Dutch family took precautions against scrofula, as follows. They cut some hair from the head of the boy who was to be protected, bored a hole in a hickory tree and sealed

it in. The brother says, "Well, Jim is safe against scrofula, anyhow."

The ideas behind both of these practices were somewhat similar and were consistent with the laws of primitive magic. According to magic, the hair and nails will grow after death and so must be the vital part of man. They gain added vitality from a growing evergreen tree—evergreen being a symbol of vitality and life, now as in the primitive days of tree worship. So the psychotic patient was to be helped by this form of magic. If part of him were revitalized, it would help his whole being.

The visitor, a plain, uneducated immigrant, had come to this country as a child. He was uneducated rather than unintelligent. He appreciated the invigorating value of the evergreen and the vital nature of hair and nails. He had a few other remedies from no one knows where. He believed in these remedies and with them he wished to help mankind. Magic never dies.

"PLAYING THE DOCTORS FOR SUCKERS"

That is the title of an editorial in a medical journal written by a doctor who had just received a circular letter from a soap concern asking the name of the soap he advised his patients to use. It reminded him of a certain famous dermatologist, a member of very high class societies, who wrote a testimonial for a certain soap. His colleagues called him to the bar of judgment. He was pronounced guilty of unethical conduct, and sentenced to one year's suspension. This occurred within the past two or three years.

A certain tobacco firm presented a large number of doctors with a carton containing 100 cigarettes. The wise ones smoked them or gave them away. The polite ones sent very nice letters of thanks. Imagine the surprise of the latter group to find themselves publicly listed as users. What could they say in protest?

A great baking company appreciating the value of the doctors' good will and friendship sent out many coupon orders, each one of which entitled the holder to one loaf of the wonderful

bread made by the company. The doctor was supposed to distribute these among his patients, who in turn presented them to their regular grocer. We doubt if many of these were used, as the profession had already been "wised up" by the "adventure in cigarettes."

Prescribing a dog is a bit uncommon. A doctor who writes in *The Hahnemannian Monthly* recalls meeting a man who introduced him to his son, a manly youth. "Doctor, here is your old patient, you cured him." "What was the matter with him?" "I do not know what you thought, but you told me to take him out of school and buy him a dog." The case record showed that the boy had an indefinite nervous complex aggravated by study. He lived in a neighborhood infested by young "hoodlums." Taking the boy from school was an obvious necessity, but was subject to the disadvantage of exposing the boy to bad companionship. Hence the suggestion to buy the dog.

THE PROGRAM OF THE DIVISION OF CANCER CONTROL OF THE NEW YORK STATE DEPARTMENT OF HEALTH

BURTON T. SIMPSON, M.D.

Buffalo

On May 1, 1930, Governor Roosevelt appointed a Special Health Commission to study and report to him concerning the administrative and legislative aspects of public health in New York State, and to submit any recommendations which the Commission believed would be of value in improving health conditions by better utilization of existing knowledge in regard to the cause, prevention, and cure of disease.

The Commission consisted of fourteen members, eight of whom were doctors of medicine. Each member was assigned a particular aspect of the problem and was allowed to form a committee chosen by himself, of persons outside the Commission, who had special knowledge of the subject. Dr. George W. Cottis of Jamestown was asked to study the cancer problem and he appointed the following physicians to work with him on his Committee: James Ewing, Howard C. Taylor, Francis C. Wood and Burton T. Simpson.

The Committee agreed that cancer has become a major public health problem because it is responsible for 10 per cent of all deaths, many of which are preventable.

In New York State, in 1900, cancer ranked eighth among the principal causes of death and accounted for 4.2 per cent of all deaths. In 1929, it ranked second, and accounted for 10.3 per cent of all deaths.

The Cancer Committee made the following recommendations to the Commission:

That there be created in the State Department of Health, a division of cancer control.

That the State and local departments of health promote the establishment of more adequate facilities for the diagnosis and treatment of cancer, including hospital care and diagnostic tumor clinics, with properly qualified physicians in charge and an adequate follow-up service.

That qualifications for pathologists engaged in tumor diagnosis and standards for pathological laboratories be prescribed by the Public Health Council, in a manner similar to the system in effect for Public Health Laboratories.

That the State Department of Health continue and extend its efforts to educate the public regarding cancer and that

voluntary associations carry out a more aggressive educational campaign in this field.

That the State division of cancer control affect a working relationship with the committee of the Medical Society of the State of New York which is sponsoring the postgraduate instruction of physicians, to develop greater knowledge and increased interest on the part of the profession in the early diagnosis and treatment of cancer.

The Legislature took definite action upon some of these recommendations. In April, 1931, the State Legislature passed a bill amending the Public Health Law, whereby there was created in the State Department of Health, a division of cancer control of which the State Institute for the Study of Malignant Diseases shall be a part. The director of the State Institute was appointed director of the division and Dr. Louis C. Kress was made assistant director.

With the approval of Commissioner Parran, the following outline of activities was adopted.

(1) A general survey of cancer distribution throughout the area of upper New York.

(2) A survey of existing facilities for the diagnosis and treatment of the cancer patient in the same area.

(3) The stimulation of the organization of diagnostic tumor clinics, and where facilities are available, treatment clinics in general hospitals.

(4) Contacts with the medical profession consisting of lectures and demonstrations before county medical societies, medical clubs, and senior medical students, teaching clinics at the Institute and personal contacts.

(5) Lay education by means of talks before civic, men and women's clubs, and other organizations, radio talks, newspaper publicity, etc.

It occurred to the author that it would be of value to discuss the program of the Division of Cancer Control and by so doing we might bring out information that would be of mutual benefit. In commenting upon the activities outlined above, it was thought desirable to make a general survey of the distribution of the incidence

of cancer throughout the State in order that we may obtain data to guide us in the establishment of facilities for the diagnosis and treatment of cancer at strategic points.

Unfortunately, no cancer morbidity figures are generally available as cancer is not a reportable disease. From the fact that the average length of life of a cancer patient is estimated as three years, it has been customary to multiply the annual deaths from this disease by three and thus roughly estimate the number of living cases of cancer.

Based upon this method there are approximately 50,000 persons suffering from cancer at all times in New York State. While we do not believe that there is such a thing as "cancer houses," we are inclined to believe from our observation that cancer is more prevalent in certain localities than in others. In any event, the facilities for the efficient diagnosis and treatment of cancer are not at this moment equally distributed.

At the present time complete tumor clinics are established and working efficiently at Buffalo, Rochester, and Albany. Diagnostic tumor clinics are being conducted at Watertown, Troy, Kingston, and Middletown. It is conceded to-day that the proper diagnosis and treatment of cancer is a group proposition and that this group should be composed fundamentally of a clinician, a surgeon, a radiologist, and a pathologist.

These clinics should be organized in connection with general hospitals, and while it is not the intention of the State to finance the clinics in any manner, the division of cancer control offers its aid in the organization of tumor clinics and the cooperation of the State Institute as a teaching and consultation center.

The necessity of the establishment of tumor clinics was recognized by the American College of Surgeons. This organization appointed a committee to study the problem and to make recommendations. The report of this committee may be found in *Surgery, Gynecology and Obstetrics*, Vol. 51, 1930. Among the recommendations was one concerning cancer clinics in general hospitals. Quoting from the report:

"The reason for the organization of these special cancer clinics is primarily the fact that the field of cancer diagnosis and cancer treatment has developed so widely in the past few years that only by the organization of a group of representatives of the different departments of the hospital, can the full resources available at the

present day for the treatment of cancer be made accessible to the individual patient. Many general hospitals are equipped with the material and apparatus needed for the treatment of cancer, including high voltage x-ray and a sufficient amount of radium, but a separate organization is required to make this equipment available for the cancer patient and to secure the necessary consultation and cooperation from the different members of the hospital staff who are interested and competent in this field."

However, the committee realized that many general hospitals did not have the facilities for radiation therapy and in such instances recommended that there be organized a diagnostic tumor clinic to provide better diagnoses upon cancer patients, to furnish group judgment concerning the proper means of therapy to be employed and to educate the medical public concerning this important group of diseases.

It was not the intention of the committee that every hospital in the community establish a tumor clinic but rather that the facilities and personnel be pooled and that by so doing, one good clinic could be maintained. In this way a larger number and variety of cancer patients could be studied.

From our many years of experience in maintaining and conducting a cancer clinic, we are in a position to be of service to any hospital or group contemplating the organization of a tumor clinic. There are many communities in upper New York State which are still without this much needed service. We shall be very glad to communicate with and give our cooperation in the establishment of clinics.

At the present time the only reliable methods we have for the treatment of cancer are surgery and radiation. These methods are efficient if the cancer is diagnosed and treated soon after its inception. Unfortunately, because of the absence of pain and discomfort in the early stages of this disease, many persons neglect those other signs and symptoms which are nearly always present and the disease becomes advanced before proper attention is given it. It is clear, therefore, that if we are to obtain better results in the control of cancer, we must spread the available knowledge to everyone concerned in the problem.

It has been said that if every doctor, dentist, nurse, and the general public, knew what he or she should know of the available knowledge concerning cancer, the mortality could be reduced 50 per cent. It is the aim of the division of cancer control to contribute its full share to realize this desirable accomplishment.

Since the American Society for the Control of Cancer is carrying on an intensive

drive in the State for the education of the lay public, it is not deemed advisable at this time, to make this phase of the program a major activity but to concentrate our energies along other lines. However, lay education will be conducted where needed and in such a manner as not to duplicate the work of other agencies.

Because of the limited number of cancer cases with which the practicing physician comes in contact, the subject of cancer is not of such great importance with him as contrasted with his other activities. The newer aspects of this disease are therefore overlooked or neglected by the average doctor. If we are to control cancer, everyone interested in the problem must do his share. Therefore we included medical education in our program as one of our major activities. From our standpoint this should include not only the practicing physicians, but also the senior medical students, the dentists, and members of the nursing profession.

One of the most obvious methods of reaching the general practitioner is through the county medical society. We are fortunate in having the backing and cooperation of the Committee on Public Health and Medical Education of the State Medical Society. This committee, of which Dr. Thomas P. Farmer is chairman, has recommended that each county society devote one meeting every year to the consideration of the cancer problem. The Division of Cancer Control has speakers available who are in active cancer work and who are conversant with the most recent knowledge regarding this subject. Demonstrations and illustrated talks have been especially prepared to present the subject of cancer control to the best advantage for the practicing physician. An idea of the character of some of our demonstrations may be obtained by visiting the scientific exhibit. These talks are not limited to county medical societies but are available to medical clubs, hospital staffs, or any group of medical men. Facilities are offered at the State Institute for physicians to acquire a knowledge of the diagnosis of cancer and its treatment by radiation therapy.

Pathologists are invited to come to our pathological laboratory to perfect themselves in the histological diagnosis of tumors. Because of recent advances in our knowledge of tumor diagnosis, the pathologist can no longer discharge his obligation by simply making a report of sarcoma or carcinoma but must be prepared to give an

opinion upon the grade of malignancy and the degree of radiosensitivity. The abundance of pathological material which reaches our laboratory each day in connection with our free diagnostic service to the physicians of the state offers an excellent opportunity for extensive study. Pathologists who are not familiar with the best method of rapid preparation of frozen sections could well devote a little time in observing our technic.

Cancer in and about the mouth is a rather common occurrence. Bloodgood has said that cancer of the mouth is a preventable disease. It is therefore important that the dentist, who has such excellent opportunity to observe precancerous and early cancerous lesions in this location, be made to realize his responsibility in the control of cancer. We are offering suitable demonstrations and are also prepared to furnish speakers to present the subject before dental societies. At the Institute we are giving regular clinics for dental students.

We believe that the senior medical student is the most fertile soil in which to implant the seed of cancer control. We have made no marked advance with the control of tuberculosis until the early signs of this disease were taught to the medical student. We are urging the deans of the medical schools to establish a definite course in cancer control. When we consider that cancer ranks second as the cause of all deaths, we cannot help but realize that this disease demands definite recognition in the curriculum of the medical college.

At the University of Buffalo such a course has been in operation for several years under the Department of Preventive Medicine. We feel sure that the ultimate results obtained from this course will offset any argument relating to an overcrowded curriculum.

Nurses have a great opportunity and also a responsibility in regard to cancer control. We are advocating instruction in this subject to schools of nursing and are prepared to offer appropriate talks to nurses' organizations.

The State of New York is primarily interested in the welfare of its citizens. The cure and prevention of disease is in the hands of the medical profession. Therefore, the state is ready to be of help in any way to the medical profession which will reflect to the benefit of the people of the state.

Anent Malpractice Suits

Although the current century has witnessed a striking rise in the average level of medical skill, paradoxically enough there has been a tremendous increase in the amount of malpractice litigation in the same period. This is due in part to a more explicit codification of the rights and duties of the physician; in part to a growing tendency on the part of the public to evade its financial obligations to the medical profession.

Our Society provides members with a twofold protection. First, they have malpractice defense, and secondly, they have a group insurance against damages which they might incur as a result of malpractice suits. To us the problem of malpractice litigation is so grave a concern that at the last session of the House of Delegates the matter was under consideration. Epitomized in a resolution, the action of the House of Delegates was to the effect that all of us shall use our best influences to discourage or prevent suits or claims against members, *except when in our best judgment such suits or claims are founded in fact upon injury to patients caused by clear negligence.*

In the summation of one's opinions and judgment, it should be remembered that the physician or surgeon who undertakes a

case impliedly represents himself as one possessing that degree of learning and skill ordinarily possessed by practitioners in his locality; and that he will use reasonable care and diligence in the exercise of such skill and learning to accomplish the purpose for which he is employed.

The law does not require that the practitioner shall be possessed of that extraordinary skill and learning which are possessed by the few, but only that general competence possessed by the average. No physician or surgeon is liable for a mere error of judgment provided he has used his best judgment. Reputable physicians and surgeons do not guarantee cures, and there is no presumption of negligence or lack of care merely because there has been an error of judgment in diagnosis or treatment, or because the particular physician or surgeon has been unsuccessful or has failed to procure a result which another physician or surgeon might have procured.

In the observation of many cases in which litigation has started, it becomes apparent that a chance remark, an unpremeditated criticism has started a patient on the road to the courts. It behooves us, therefore, to be circumspect in our conduct, lest unwittingly we become agents in harming our colleagues. Very often, when tempted to criticize, resort to conference with the physician who was in prior attendance upon the case changes the patient's story and invalidates the criticism.

Finally, to remove another factor which conceivably might influence malpractice litigation, the House of Delegates has ruled that *"no member of this Society shall make a charge or receive any compensation for his services based upon the outcome of any malpractice suit or claim in which he shall appear as a witness."*

Let us be sure that the physician violated some duty which he owed his patient, which in itself produced the results of which complaint is made, let us make sure that the patient himself was free from any fault or neglect which might have induced his present plight, and let us so act in the consulting room, that casual comment cannot be mistaken. Before all, let us not make any patient feel that only we, ourselves, could have been his medical savior.

population over 40 years of age are completely disabled by chronic maladies, and, not counting the victims of tuberculosis and mental disease, over 0.3 per cent are receiving some care from medical or social agencies because of incapacity due to chronic illness.

To meet this unfortunate situation, the Committee recommends, for one thing, a modern hospital in New York City for chronic diseases. No less than 20 per cent of the beds of general hospitals, it appears are now used for victims of chronic illness, and "most of these could be treated more economically and with better results" in such a special institution. The only provision now made by the city for the chronic sick are Neurological Hospital, Cancer Institute, and the chronic wards in three other hospitals, "all of which are inadequate for this purpose."

We all know only too well how often the best solution of a problem meets a snag because it turns out to be against some rule or regulation. Well, it happens again here. The committee believes that "many of the chronically ill could be cared for just as well at home and would be happier there." Home care, indeed, "is not only more humane for many patients, but it is also much more economical than institutional provision." And what is more, a survey shows that four-fifths of the patients living at home do not need institutional care, several hundred patients in general hospitals might be taken care of at home, and undoubtedly more in other institutions could be at home. Here, however, we strike the snag. The city provides at present only institutional care for the chronic sick, because home care paid for out of public funds is not permitted under the city charter. Besides, the committee remarks sagely, "one question to be met is whether a system of home care free from political abuse can be conducted in a city the size of New York." The committee certainly "said something" when they said that.

At any rate, the anomalous condition of this unfortunate group is now squarely in the limelight, and we may expect that something will be done to remedy it. The committee is composed of the kind of people who get things accomplished, they

have given their findings and recommendations to Commissioner Goldwater, who has the same excellent trait, and their ideas and plans have been endorsed by the New York Academy of Medicine, the United Hospital Fund, the New York City Visiting Committee of the State Charities Aid Association, and the Executive Committee of the Welfare Council of New York City.

Probably very few, if any, of the indigent chronic sick themselves have the faintest idea of all this effort going on far over their heads to better their care. Some day they will merely find that they are more comfortable, that they are in a fine new building, with medical and nursing attention that is better suited to them. It may very likely happen that not one of the committee who are working to bring this about will ever receive a word of thanks from these unfortunates whose burden of illness is made a bit lighter, a bit more endurable. But the workers are not looking for thanks. If the days of pain are eased, that is reward enough. And the weight of power back of this plan seems to indicate that the happy result is not far away.

Worse than the Great Plagues

When we cure one evil, another appears. We defeat death in one form; he comes back in a different guise. We blot out cholera, yellow fever, and plague, only to see heart disease, cancer, pneumonia, and nephritis claim their hundreds of thousands. Able men are battling these diseases, and it is not beyond possibility that the future may see them conquered.

But while we are fighting these foes of the human race, man himself is devising new dangers that threaten his own life. Man's enemy has always been man, to some extent, but never has his peril reached the height where it is now. Our mechanized civilization is destroying its tens and hundreds of thousands and leaving a wake of crippled and disabled victims as a sad legacy for the physician and surgeon to patch up. Man's own machines have become Franksteins to turn and slay him.

We shudder at the great plagues that ravaged the populations of the Middle Ages, but a speaker at the recent annual meeting of the Massachusetts Medical Society re-

marked that the mechanical monsters of to-day are "far more perilous than all the plagues of the past." It is a bit disheartening to the earnest and devoted physician whose life is dedicated to the war on disease, to see the seeming public indifference to the continuous slaughter that goes on, year in and year out, on the highway and among the whirling wheels in the factory.

What makes this subject timely just now is the fact that the mortality reports coming into the home office of the Metropolitan Life Insurance Company indicate that more people were killed by automobiles in the first three months of 1934 than in the same period of any previous year. The automobile death rate, indeed, is almost 20 per cent higher than last year, and 8 per cent higher than it was in 1931, the previous high year. And, moreover, the added victims seem to be the little folks, for so far this year the automobile fatality rate among children is 26 per cent above last year's mark. In the last ten years it seems that over 275,000 persons have been killed by automobiles, and in the last four years nearly 4,000,000 have been injured. This contrasts sharply with the 50,000 American soldiers who were killed or died of wounds in the World War.

It was pointed out in the paper read before the Massachusetts Medical Society by Dr. Lincoln Davis that the Census Bureau figures for 1929 show over 94,000 deaths from all forms of accidents, over 16,000 suicides, and nearly 10,000 homicides, a total of 120,000 violent deaths. Heart disease, with its toll of 245,000 lives, is the only greater cause of death. Next comes cancer, with 111,000 victims and pneumonia and nephritis with 106,000 each. Where are the great epidemic scourges of the past? In 1929 only 151 persons died of smallpox, 19 of typhus, none of plague, none of yellow fever, none of cholera.

Here, then, we have a formidable peril to mankind, caused by—man himself. No germicide, no vaccine will reach it. The cause is social, the cure must be social. But if the cause is not medical, the effect is, and it is felt immediately when the hurry call summons the physician to the victim's bedside. So the doctor has a

double interest. He has a right to protest as a health guardian against this continuous wrecking of humanity, this breaking of bodies upon the wheels of pleasure and industry, and he has a right as a man, a citizen, to call a halt on a reckless waste of human life that makes war seem like a comparatively safe pastime.

More and more the doctor's horizons are broadening, and his field is extending to take in larger areas of human life. The health of his people is conditioned by everything that touches their welfare. He can say with the old Roman, "Nothing human is alien to me." Here is something that may well engage his concern.

THE BUDGET

The following budget of expense of the Medical Society of the State of New York for the year beginning July 1, 1934, and ending June 30, 1935, was approved by the Trustees on June 19, 1934, in accordance with Chapter VI, Section 2, of the By-Laws.

LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

Death Action—Physician's Responsibility

A case which very well illustrates the nature of the legal responsibility of a physician for the death of a patient was recently decided in one of the Southern States. The facts of the case must be detailed at some considerable length for an understanding of the decision.

The explosion of a lamp caused severe burns to one S, and he was taken to a certain sanatorium to receive treatment. He came under the care of a certain Dr. H. The doctor found that the burns covered at least 60 per cent of his entire body and that they were, in the main, second and third degree burns. The most serious were on his abdomen, chest and side. Apparently while at the sanatorium the patient was in great pain, became delirious, and made a great deal of noise, causing considerable disturbance and occasioning discomfort to other patients in the sanatorium.

After S had been under his care for a week, Dr. H. made a trip to a neighboring town and consulted with a Dr. C. who was in charge of an insane asylum with a view to having the patient transferred to that institution. A full history was given to Dr. C., including the nature and extent of the patient's burns, and the delirious mental condition. Dr. C. was of the opinion that the patient was not legally insane, but expressed the feeling that his institution was better equipped to care for S than the sanatorium. He told Dr. H. that he would be glad to arrange to receive the patient if Dr. H. could secure proper commitment papers from the County judge. Dr. H. then consulted the County judge and was told that the patient should be brought before medical examiners in his town before the question of commitment could be decided.

Dr. H. thereupon returned to the sanatorium, and sent the patient in an ambulance accompanied by nurses to be passed upon by the medical examiners. They, however, reported that S was not insane, but simply delirious from pain as a result of his burns, and on their report the judge declined to issue the necessary papers committing the patient to the State institution.

The ambulance driver, however, proceeded on with the patient to the asylum. Dr. C. at the said institution refused to receive him without the required papers, and nothing was done for the patient there except that a hypodermic of morphine was given him to alleviate his pain. The driver then, upon instructions from Dr. H., brought the patient back to the sanatorium, and he returned to the care of Dr. H.

About four days after the futile trip, the patient developed hypostatic pneumonia, and died a few days later. The cause of death given at the sanatorium was the burns together with the pneumonia.

An action was thereafter brought on behalf of the widow and children of the deceased against the sanatorium and Dr. H. to recover for damages sustained as a result of the alleged improper handling of the case.

Upon the trial the plaintiffs introduced a considerable amount of testimony to the effect that the unfortunate ambulance ride had been made at a reckless, high speed over rough roads. Said testimony was controverted by the nurses and the driver, and it was further brought out that the ambulance was of the most modern type and was well equipped with all devices for the safety and comfort of a patient riding therein.

Two doctors called by the plaintiffs testified that the trip could not have been good for the patient, and that it could have resulted in pneumonia developing. However, those doctors on cross examination testified that it would be lobar pneumonia that would so result, and which would develop between twenty-four hours and a maximum of seventy-two hours after the ride. The uncontroverted testimony on behalf of the defendants was that the type of pneumonia that actually developed was hypostatic, and that that was the result of the patient having to lie in one position an unusual length of time, and from bad circulation and bad heart action as the result of the burns.

The proof in the case failed to establish any responsibility on the part of the sanatorium and the trial court directed a

marked that the mechanical monsters of to-day are "far more perilous than all the plagues of the past." It is a bit disheartening to the earnest and devoted physician whose life is dedicated to the war on disease, to see the seeming public indifference to the continuous slaughter that goes on, year in and year out, on the highway and among the whirling wheels in the factory.

What makes this subject timely just now is the fact that the mortality reports coming into the home office of the Metropolitan Life Insurance Company indicate that more people were killed by automobiles in the first three months of 1934 than in the same period of any previous year. The automobile death rate, indeed, is almost 20 per cent higher than last year, and 8 per cent higher than it was in 1931, the previous high year. And, moreover, the added victims seem to be the little folks, for so far this year the automobile fatality rate among children is 26 per cent above last year's mark. In the last ten years it seems that over 275,000 persons have been killed by automobiles, and in the last four years nearly 4,000,000 have been injured. This contrasts sharply with the 50,000 American soldiers who were killed or died of wounds in the World War.

It was pointed out in the paper read before the Massachusetts Medical Society by Dr. Lincoln Davis that the Census Bureau figures for 1929 show over 94,000 deaths from all forms of accidents, over 16,000 suicides, and nearly 10,000 homicides, a total of 120,000 violent deaths. Heart disease, with its toll of 245,000 lives, is the only greater cause of death. Next comes cancer, with 111,000 victims and pneumonia and nephritis with 106,000 each. Where are the great epidemic scourges of the past? In 1929 only 151 persons died of smallpox, 19 of typhus, none of plague, none of yellow fever, none of cholera.

Here, then, we have a formidable peril to mankind, caused by—man himself. No germicide, no vaccine will reach it. The cause is social, the cure must be social. But if the cause is not medical, the effect is, and it is felt immediately when the hurry call summons the physician to the victim's bedside. So the doctor has a

double interest. He has a right to protest as a health guardian against this continuous wrecking of humanity, this breaking of bodies upon the wheels of pleasure and industry, and he has a right as a man, a citizen, to call a halt on a reckless waste of human life that makes war seem like a comparatively safe pastime.

More and more the doctor's horizons are broadening, and his field is extending to take in larger areas of human life. The health of his people is conditioned by everything that touches their welfare. He can say with the old Roman, "Nothing human is alien to me." Here is something that may well engage his concern.

THE BUDGET

The following budget of expense of the Medical Society of the State of New York for the year beginning July 1, 1934, and ending June 30, 1935, was approved by the Trustees on June 19, 1934, in accordance with Chapter VI, Section 2, of the By-Laws.

	Appropriation
Rent	\$2,600.00
Telephone	200.00
Postage	500.00

Stationery, Printing, and Expenses....	500.00

on, and treated the man thereafter for burns. Subsequent thereto an action was brought against the doctor charging him with having been responsible for the burns which the patient sustained. The action came on for trial and plaintiff testified in court that after the doctor had finished bandaging the arm he took a colorless liquid and poured it over the entire bandage and failed to caution him that the bandage was inflammable. He claimed that the entire bandage, upon lighting his cigaret, went up in flames resulting in severe and serious burns to both hands.

At the close of all the testimony the trial judge directed a verdict in favor of the defendant, thereby exonerating him from all responsibility for the burns which the plaintiff sustained.

Claimed Failure to Detect Glaucoma

A middle-aged man consulted a physician specializing in eye, ear, nose, and throat work, complaining that his glasses were not suitable for his eyes. The doctor made a thorough test of his eyes and found that the patient at 15 ft. distance with slight correction was able to read the doctor's chart properly. He found the patient's near vision to be perfect.

The doctor's examination of the patient also consisted in the use of the ophthalmoscope and tonometer. Light tests indicated that the patient's pupils were normal, and further tests showed that his field of vision was normal. The doctor prescribed proper glasses for the patient and he never saw him thereafter.

A malpractice action was instituted against the doctor in which the claim was made that the doctor failed to properly examine the patient's eyes and that he failed to detect that the patient was suffering from glaucoma in both eyes, and that as a result of the doctor's failing to detect said condition, which it is claimed could have been corrected at that time, the plaintiff claimed to have completely lost the use of his left eye and that the sight of his right eye had become greatly impaired. The plaintiff further claimed that as a result of the negligence of the defendant, eventually he would lose the sight of both eyes, and that in all probability both eyes would have to be removed.

Upon the trial of the case before a judge and a jury, the plaintiff introduced the testimony of an optometrist who claimed that

he examined the plaintiff at about the same time that the defendant had done so, and at that time he found definite cupping of the optic nerve, hardness of the eyeballs, complaints of steam before the eyes and rainbow-like rings around lights. The optometrist claimed that he made a diagnosis of glaucoma. The defendant, on the other hand, testified that at his examination there were no symptoms of glaucoma, and that the man made no complaints compatible with glaucoma. The plaintiff himself testified that about nine months after he had consulted the defendant, he woke up one morning to find that he was blind in one eye and suffering intense pain, and that he consulted another specialist who treated him for glaucoma.

The case was sent to the jury and a verdict rendered in favor of the defendant doctor, thereby exonerating the doctor from all charges of malpractice, and rejecting the proof offered by the plaintiff and his witnesses.

Failure to Determine Presence of Particle of Glass

A general practitioner was called to the home of a young man about 20 years of age, and he found the patient lying upon his stomach on the sofa with a bleeding wound in his buttocks.

The doctor was given the history that the patient had received the injury by falling on a glass bottle. He found a laceration about an inch long, but not particularly deep in the buttocks close to the rectum, but not involving the rectum. The doctor made a careful examination with his fingers and with forceps to find whether any particles of glass remained in the wound; but he did not find any such particles. He cleaned out the wound and drew the edges together and applied two sutures. He dressed the wound with a pad held with adhesive strips. He saw the patient and redressed the wound on several occasions, and the wound healed very well. About three weeks after he first had seen the patient, the patient came into his office complaining of soreness where the sutures had been. The doctor examined him and found a hard lump under the skin which he decided was probably a piece of glass that he had been unable to detect. He referred the patient to the accident ward of a nearby hospital for surgical treatment.

verdict in its favor. However, on the state of the proof set forth above, the case was sent to the jury, and a verdict was rendered in favor of the plaintiffs against Dr. H. Appeals were taken by both parties from the judgment of the trial court, with the result that the decision dismissing the case against the sanatorium was affirmed, and the judgment against the doctor was reversed and the case ordered dismissed as to him as well.

The Appellate Court, so far as concerned the sanatorium, readily found that its duty was simply that of providing a room and meals and nursing; but that it was under no duty to provide medical or surgical treatment to the deceased and that it could therefore not be held to responsibility for any acts of Dr. H. as the doctor in charge of the case.

After considering the case as to Dr. H., the Appellate Court came to the conclusion that the plaintiffs had failed to establish their burden of proof. They were bound to prove, not merely that the negligence of the defendant doctor had injured the patient, or added to his suffering, but with certainty that his negligence had caused the death of the patient. In deciding that the doctor had not been shown to be responsible for the death, the Court said:

"We have made a careful search of all the evidence contained in the record to discover if there is any conflict in the evidence as to whether or not the plaintiff's intestate's death was caused by the trip which the patient took in the ambulance from J. to the Hospital for the Insane and return There is some evidence in the record to the effect that the patient suffered more or less pain from the jolting of the ambulance, and according to the evidence of two of the witnesses who were in the ambulance on the trip with the patient, the patient showed evidences of suffering; and that the ambulance was driven in a reckless way and manner, and the patient was jolted considerably, and the burns were caused to crack open and to exude bloody water, and that the patient was partly conscious of the pain at times, although for the greater portion of the time the patient was delirious. However, there is no evidence in the record that this trip could have resulted in the patient developing hypostatic pneumonia. The nearest suggestion of the trip resulting in pneumonia is the evidence of Dr. D. and Dr. C. Both these doctors admitted that the trip would not have caused pneumonia of the type known as hypostatic. The evidence in the record is undisputed that the patient died on account of the serious burns and the effects of the burns and of hypostatic pneumonia. We are also of the opinion, as above set forth, that all the evidence by the several medical experts who testified in the case showed that Mr. S. would have died as the result of the serious burns regardless of the trip from J. to the asylum and back, and

regardless of the medical treatment; that the burns were of such a character as would inevitably result fatally to the patient.

"If it be conceded that the trip in the ambulance was shown to be unnecessary and improper, and for insufficient reason, and therefore Dr. H. was negligent in sending the patient from J. Sanatorium, and if it be further conceded that this trip caused the patient additional physical pain and suffering, and rendered the patient more uncomfortable, the fact remains that according to the evidence this did not contribute to the death of Mr. S. It only operated to his physical pain and discomfort.

"In this view of the case we do not think that there was any evidence to warrant the jury in arriving at the conclusion that this trip in the ambulance was the cause, or a contributory cause of the death of plaintiff's intestate."

While this case is one which might very well create a strong sympathetic appeal in the minds of a jury in favor of the plaintiffs, the Appellate Court's ruling that no case was proved was undoubtedly correct. In an action to recover damages based upon a claim of death caused by a wrongful act, the plaintiff must show not only a mere wrongful act, but must show that the death resulted therefrom.

Burns Due to Bandage Catching Fire

A young man employed as a dishwasher in a restaurant injured the back of his hand when an object fell upon it and was sent to the office of a surgeon for the purpose of determining whether he had sustained a fracture. The doctor examined him carefully and found that there was no fracture present, but that there was an inflammation of the tendons on the back of the left wrist. The doctor decided to put on a splint and rubbed the patient's arm and wrist with alcohol for the purpose of cleaning the same, and after the alcohol had dried, he took some cotton, packed it around the arm, and applied a piece of gauze over the patient's hand. Then he applied a splint to the palm and back of the hand from the hand to the elbow, bandaged the hand and forearm with gauze, and permitted the patient to go.

Some minutes later the patient returned to the doctor's office and told the doctor that he had struck a match for the purpose of lighting a cigaret and that the cotton on the bandage had caught fire, and that in attempting to put out the flame he had burned his good hand. The doctor found the cotton scorched but not burned away and found a slight burn on both hands. He took off the bandage, put a new one

on, and treated the man thereafter for burns. Subsequent thereto an action was brought against the doctor charging him with having been responsible for the burns which the patient sustained. The action came on for trial and plaintiff testified in court that after the doctor had finished bandaging the arm he took a colorless liquid and poured it over the entire bandage and failed to caution him that the bandage was inflammable. He claimed that the entire bandage, upon lighting his cigaret, went up in flames resulting in severe and serious burns to both hands.

At the close of all the testimony the trial judge directed a verdict in favor of the defendant, thereby exonerating him from all responsibility for the burns which the plaintiff sustained.

Claimed Failure to Detect Glaucoma

A middle-aged man consulted a physician specializing in eye, ear, nose, and throat work, complaining that his glasses were not suitable for his eyes. The doctor made a thorough test of his eyes and found that the patient at 15 ft. distance with slight correction was able to read the doctor's chart properly. He found the patient's near vision to be perfect.

The doctor's examination of the patient also consisted in the use of the ophthalmoscope and tonometer. Light tests indicated that the patient's pupils were normal, and further tests showed that his field of vision was normal. The doctor prescribed proper glasses for the patient and he never saw him thereafter.

A malpractice action was instituted against the doctor in which the claim was made that the doctor failed to properly examine the patient's eyes and that he failed to detect that the patient was suffering from glaucoma in both eyes, and that as a result of the doctor's failing to detect said condition, which it is claimed could have been corrected at that time, the plaintiff claimed to have completely lost the use of his left eye and that the sight of his right eye had become greatly impaired. The plaintiff further claimed that as a result of the negligence of the defendant, eventually he would lose the sight of both eyes, and that in all probability both eyes would have to be removed.

Upon the trial of the case before a judge and a jury, the plaintiff introduced the testimony of an optometrist who claimed that

he examined the plaintiff at about the same time that the defendant had done so, and at that time he found definite cupping of the optic nerve, hardness of the eyeballs, complaints of steam before the eyes and rainbow-like rings around lights. The optometrist claimed that he made a diagnosis of glaucoma. The defendant, on the other hand, testified that at his examination there were no symptoms of glaucoma, and that the man made no complaints compatible with glaucoma. The plaintiff himself testified that about nine months after he had consulted the defendant, he woke up one morning to find that he was blind in one eye and suffering intense pain, and that he consulted another specialist who treated him for glaucoma.

The case was sent to the jury and a verdict rendered in favor of the defendant doctor, thereby exonerating the doctor from all charges of malpractice, and rejecting the proof offered by the plaintiff and his witnesses.

Failure to Determine Presence of Particle of Glass

A general practitioner was called to the home of a young man about 20 years of age, and he found the patient lying upon his stomach on the sofa with a bleeding wound in his buttocks.

The doctor was given the history that the patient had received the injury by falling on a glass bottle. He found a laceration about an inch long, but not particularly deep in the buttocks close to the rectum, but not involving the rectum. The doctor made a careful examination with his fingers and with forceps to find whether any particles of glass remained in the wound; but he did not find any such particles. He cleaned out the wound and drew the edges together and applied two sutures. He dressed the wound with a pad held with adhesive strips. He saw the patient and redressed the wound on several occasions, and the wound healed very well. About three weeks after he first had seen the patient, the patient came into his office complaining of soreness where the sutures had been. The doctor examined him and found a hard lump under the skin which he decided was probably a piece of glass that he had been unable to detect. He referred the patient to the accident ward of a nearby hospital for surgical treatment.

Two days later the doctor called at the patient's house and was shown a sliver of glass about an inch long and a quarter of an inch wide which had been removed at the hospital. Thereafter the wound promptly healed and the patient apparently sustained no further ill effects.

An action was instituted against the doctor charging him with malpractice in that he failed to remove the particle of glass on the occasion of his first visit. The case came on for trial before a judge and a jury, and upon the trial the plaintiff, by his witnesses, failed to show that the doctor in his treatment of the case was in any way careless. The Court, therefore, at the close of the plaintiff's testimony dismissed the action.

Claimed Failure to Detect Bullet in Finger

A boy thirteen years of age was brought to a doctor's office accompanied by his mother. The doctor was told that the boy had been playing with fire crackers and hurt his finger. The doctor found the high index finger swollen and made a diagnosis of infection. He requested the mother to take the boy to some hospital, which she refused and he also advised that an x-ray be taken, which was also refused.

The doctor obtained some tetanus antitoxin and administered to the boy 1,500 units. He applied to the finger wet dress-

ings with chlorazene solution and told the mother to keep the finger dressings saturated with magnesium sulphate solution. The next day the doctor again saw the boy and renewed the wet dressings, and although he requested the boy to return for dressings daily, he did not do so, coming only at infrequent intervals to the doctor's office. When the doctor last saw the boy, about two weeks after the first visit, the swelling was diminished and no mass was felt. Wet dressings were applied at that time and the child was requested to return the following day, but he did not do so. The doctor heard nothing more of the case until two years later when the child's mother told him that he had failed to remove a bullet from the patient's finger. When the doctor treated the patient there was no evidence of any foreign body of any kind, and it seemed impossible that a bullet could have penetrated the finger where there was no breaking of the flesh.

A malpractice action was brought against the doctor charging him with failing to observe the presence of a bullet and removing the same from the patient's finger. The case came on for trial before a judge sitting without a jury, and after all the testimony had been put in, the court directed a judgment in favor of the defendant, finding that the plaintiff had failed to prove that the defendant had been in anyway negligent in the treatment of the case.

DOCTORS AS ANGEL-MAKERS

A Kentucky Congressman addressing the Medical Association of his State told the doctors that "as I look back over the lapse of years I know that you folks have made more angels than all the preachers." When the laughter subsided, the Congressman went on to imagine a visit to heaven, where he met a youthful spirit and asked: "Son, how did you get to be an angel?" And with a smile at Dr. Martin, the President of the Kentucky doctors, who was seated nearby, the Congressman went on to report the answer of the little cherub, who said: "Well, do you know this fellow Dr. Martin from Harlem, who is now the President of the Kentucky State Medical Association, being installed today?" "Yes, oh yes, I know the Doctor quite well; old friend of mine. I have enjoyed the hospitality of his home at Harlem. He is a good fellow."

"Well, I'll tell you how I happened to be an angel. Some years ago I went out with a lot of other boys in the neighborhood, and we saw a neighbor's orchard, and the green apples were hanging from the boughs of the trees, and as we looked at those apples each one was invested with a flavor and an aroma which must have

been like that which clung to the cup where Hecuba served nectar to the gods. We leaped the fence and we ate a lot of those apples, and after a while an insurrection and a rebellion arose in my department of the interior and my parents thought someone should be called in to quell the insurrection, so Dr. Martin was called. Doctor looked me over carefully, and after a while he gravely shook his head and said, 'An operation is necessary; it is appendicitis.' So the doctor got out his carving knives, sharpened them up, removed my appendix from my anatomy, took \$250 from the purse of my parents, and gave me a through ticket to the realm of bliss and here I am an angel now because of Dr. Martin." (Laughter).

Insurance agents send their representatives to us for inside information concerning our patients, take our time and expect it to be given free. In the meantime, remarks this doctor in *The Hahnemannian Monthly*, each and all of them are actively engaged in promoting schemes for massed insurance and socializing of medicine. And what can we do about it?

BOOKS REVIEWED

Neuroanatomy.—A Guide for the Study of the Form and Internal Structure of the Brain and Spinal Cord By J H Globus, M.D. Sixth Edition Quarto of 240 pages, illustrated Baltimore, William Wood & Company, 1934 Cloth, \$5.50

This revised students' stand by offers an original and sensible method of presenting the practical study of brain anatomy. The up-to-date character of the book is reflected especially in its outlook. As a guide it serves the purpose of a dissector's atlas for the brain. Through out the sequence of sections, however, there is a running interpretation of the connected functions represented by the various parts studied and, in addition, there are concise and well-directed questionnaires appended which may be used by the student as a basis for further reading in neurology and physiology. Although the book manifests little of the consciously didactic attitude, the sectional discussions amply describe the topography and the tracts variously presented in the brain sections. It is this composite service as guide, atlas, and textbook which recommends the book. There is a good supply of unfilled outlines and drawings which serve the student as practice and study forms.

SAM PARKER

Influenza.—By David Thomson and Robert Thomson Quarto of 640 pages illustrated Baltimore, Williams & Wilkins 1933 (Volume IX, December, 1933, of Annals of the Pickett Thomson Research Laboratory, Monograph XVI, Part 1)

In the complete monograph of which this Part 1 the contents of over 4,000 papers have been abstracted and organized and the writers believe that to make libraries complete, a series of volumes similar to this one is needed on various subjects in medicine, to condense and organize the tremendous number of papers and books which accumulate over a period of years.

Early chapters deal with the nomenclature of the disease, antiquity, lists of great epidemics and a review of the literature of these. The clinical character, varieties and symptoms of influenza are described in minute detail. Data may readily be found regarding any symptom of the disease as for example bradycardia, tachycardia or arrhythmias. The interesting subject of cardiac complications and sequelae will be discussed in the second part.

This is indeed a monumental work for reference and shows evidence of tremendous industry.

W. E. McCOLLUM

Health Education in an American City.—An Account of a Five Year Program in Syracuse, N. Y. By Louise T. Bache Octavo of 116 pages, illustrated Garden

City, N. Y. Doubleday Doran & Company 1934 Cloth, \$2.00 (Published for the Milbank Memorial Fund)

This book describes the activities which the author supervised in Syracuse, during the Milbank Fund 'Health Demonstration'. It relates in detail the manner in which concerted effort may be made to educate the public in relation to health matters, promulgated by a local Health Department.

In form it is much like a primer, and perhaps intended as a guide to minor department employees as well as department heads, at least it so impressed the reviewer. The careful outlining of detail should save future demonstrators much trouble, aiding them in avoiding "trial and error" methods.

As is usual in this type of publication, there is a paucity of the words "medical profession". It is the family doctor who must in the end be the one who continues to be the advisor of the family in health matters even though it be only by means of the casual word dropped in making his rounds.

Health authorities may well begin a campaign such as this book describes by a few get-togethers with the profession.

FREDERICK S. WETHERELL

The Practical Medicine Series.—Comprising Ten Volumes on the Year's Progress in Medicine and Surgery Series, 1933 Chicago, The Year Book Publishers [c. 1933]

The 1933 Year Book of the Eye, Ear, Nose and Throat. The Eye, edited by E. V. L. Brown, M.D., and Louis Bothman, M.D. The Ear, Nose and Throat edited by George L. Shambaugh, M.D., and Elmer W. Hagens, M.D. 12mo of 632 pages, illustrated Cloth, \$2.50

The material, while not complete, does cover very well the more important contributions of American and foreign journals. Only rarely does an abstract appear of a worthless study. It is encouraging to note that functional testing of the auditory apparatus has not gone entirely out of style. An interesting group of studies is reported on nasal functions which helps one to understand the increased susceptibility to "common colds" when home heating plants are started each fall.

One becomes more and more enthusiastic over this little work as the years go by which brings forth more and more useful information. It is a book well worth frequent perusal.

JOHN N. EVANS

Curing Our Nerves.—By Marshall M. Cloud, M.D. Octavo of 206 pages Pasadena, Cal., Pasadena News Syndicate Publishers 1934

In spite of the author's claim that this book "will be of great value to the nurse and physician in their man-

agement of nervous cases," it "can be understood by any one," his statements are disjointed, contradictory, unscientific, and essentially dangerous. His general thesis is that alcohol and tobacco should never be indulged in, and that venereal disease causes everything. He lists as the cause of nervousness everything from amebiasis to eye strain, and Virgil to Pasteur—in fact, makes it impossible for anyone to escape nervousness, and then advises that he can cure all. It is interesting to note that "Nervous persons often have a fear of being alone, and are in great distress as soon as they are left alone. This can be removed by having company about." He recommends in general the reading of the Bible: "If you are unable to clearly draw the line in your own mind of what to do and what not to do, I would say, . . . read and study the Ten Commandments . . . then read the Book of Hebrews in the New Testament."

If the physician wishes to create a neurotic, there is no doubt that this book would act as an excellent etiological agent.

J. L. McCARTNEY

The 1933 Year Book of Radiology.—Diagnosis, edited by Charles A. Waters, M.D. Therapeutics, edited by Ira I. Kaplan, M.D. Octavo of 804 pages, illustrated. Chicago, The Year Book Publishers [c. 1933].

This second Year Book, is of the same high standard as that of the first year. The subject matter selected under Dr. Water's editorship represents the latest advances in the diagnostic fields, and the correlation of the clinical and roentgenological aspects is extremely valuable.

The study of the glandular system with reports of the results of calcification of the suprarenals in Addison's disease, the studies of the breasts and of the pharynx are noteworthy. The section on respiratory and cardiovascular disturbances with its illustrations of case reports, as well as the roentgenological findings, comprise a valuable textbook on these subjects. The chapters on technic and teaching are very valuable. In the section on therapeutics, Dr. Kaplan's introductory remarks are valuable as a resumé of radiotherapeutic rationale. His "general considerations" represent present-day knowledge of cancer with the results from many sources in the care of such patients. The whole book represents the advances of the last year in the fields of radiological diagnosis and therapeutics and its possession is essential for one who would keep up-to-date in these fields.

The publishers work, with its good paper, clear type and illustrations is praiseworthy. The placing of the illustrations closer to the context corrects a fault found in the first volume.

C. EASTMOND

Lymphatics, Lymph and Tissue Fluid.—By Cecil K. Drinker, M.D., and Madeleine E. Fields, Ph.D. Octavo of 254 pages. Baltimore, The Williams & Wilkins Company, 1933. Cloth, \$3.00.

This volume of about 250 pages is practically a critical survey of experimental data on the anatomy, pathology, immunology and especially the physiology of the lymphatics, lymph, and tissue fluids of the mammalian body.

The authors accept the theory of the closed tube structure of the lymphatics and quote Dr. Sabin's recent confirmation of this theory. The entrance of foreign particles and colloidal solution into the lymphatics is discussed at length. The chapters on the flow and composition of lymph, as well as on tissue fluids, contain charts with experimental data, all of which are critically analyzed.

The concluding chapter is on practical considerations, which includes a survey of the role of the lymphatics in inflammations due to infection. Antecedent inflammation tends to block lymph entrance which, however, may be enhanced by movement or massage of the affected parts. There is, however, a conspicuous lack of clinical observations in this chapter to confirm or disprove the various experimental observations.

SILIK H. POLAYES

The Nature of Disease Journal.—Vol. 2. By J. E. R. McDonagh, F.R.C.S. Octavo of 196 pages. London, William Heinemann, Ltd., 1933. Paper, 7s. 6d.

The author has undertaken to view diseased processes from the viewpoint of physical and colloid chemistry. The blood is studied almost exclusively by measuring suspension stability, refractive index, sugar, urea, cholesterol, calcium, and the ultramicroscopic pictures of the serum. Many highly speculative viewpoints are presented. An attempt is made to resolve

physiologic and pharmacologic processes into their colloid and crystalloid components. The effects of drugs and diseases on the dispersion of the tissue colloids are speculated upon and clinical cases are cited as illustrative of various types of reactions.

DAVID GLUSKER

Public Health Nursing in Industry.—By Violet H. Hodgson, R.N. Prepared for the National Organization for Public Health Nursing. Octavo of 249 pages, illustrated. New York, The Macmillan Company, 1933. Cloth, \$1.75.

This book covers the field of industrial nursing in a very comprehensive and detailed manner. It brings out and answers all the questions that may arise in industrial medicine. A nurse who is interested in this phase of medicine, would do well to study this work. It is ideal preparation for one who is anxious to know the details of industrial organization and the problems that are concerned from a health standpoint.

J. J. WITTMER

The Nature and Treatment of Amentia.—By L. Pierce Clark. Octavo of 306 pages. Baltimore, William Wood & Company, 1933. Cloth, \$4.25.

The work of the late Dr. Clark is based upon a rich experience in the field of mental deficiency, and presented in the light of psychoanalytic interpretation. The introductory chapter is devoted to the basic principles of psychoanalysis. The remainder is a description of the different aspects of mental deficiency, and throughout, there is the psychoanalytic implication of the basic drive in the behavior of the amentia patients. Many illustrative cases are described.

The unique way of the presentation of the subject should stimulate further and renewed interest in the subject.

IRVING J. SANDS

Treatment of the Commoner Diseases Met With by the General Practitioner.—By Lewellys F. Barker, M.D. Octavo of 319 pages. Philadelphia, J. B. Lippincott Company [c. 1934]. Cloth, \$3.00.

Among many other subjects the author covers the following: Constitution and Environment; Immunity and Allergic Reactions. The Common Cold and the Treatment of Hay Fever are handled quite briefly. Pneumonia is rather thoroughly covered. Tuberculosis receives many pages from all angles. The Cardiac Disorders are thoroughly and intelligently discussed. Rather complete data are given on the Anemias.

The treatment of gastric conditions is handled in a rather orthodox manner. The subject of colitis receives less space than might be given to this interesting and perplexing malady. The use of ammonium chloride and kindred drugs is not even mentioned in the discussion of the treatment of kidney diseases. Considerable space has been given to arthritis in its many forms and types. The neurological conditions have been very well covered. In the treatment of the chapter on metabolic, and food and Vitamin deficiency disease, the author deserves special mention for his excellence of presentation.

On the whole the book is worthwhile. We realize how difficult it is to cover the entire field of therapy adequately when so many new ideas for therapy are being brought out almost daily.

BENJAMIN M. BERNSTEIN

Maternal Mortality and Morbidity.—A Study of Their Problems. By J. M. Munro Kerr, M.D. Octavo of 382 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$8.25.

When this book was published Kerr had not seen the New York Committee Report on Maternal Mortality, but it is well known that the Reports of the Departmental Committee on Maternal Mortality and Morbidity show about the same figures; it is on these British reports that much of the discussion in this book is based. It is interesting to note, however, in his chapter on domiciliary service, that he recommends that all primigravidae, with few exceptions, be delivered in a hospital, and that all women in whom previous delivery was in any way abnormal or difficult should be advised to enter a hospital for subsequent delivery. No operative treatment, except of a minor nature should be undertaken in the patient's home unless her condition is such as to contra-indicate removal to an institution.

A very valuable book, easily and quickly read, and of great interest to obstetricians and other students of the problem of maternal welfare.

CHARLES A. GORDON

THE PREVENTION OF ASPHYXIA DURING ANESTHESIA

PALUEL J FLAGG M D

New York City

The problem of preventing asphyxia in anesthesia may perhaps be best approached as follows

Let us first consider the common causes of asphyxiation. We may then suggest the means of relieving these causes by modern technical methods

Two fundamental causes of asphyxia, or oxygen want, are generally recognized. First, the physical or mechanical, second, the biochemical

The first group of causes—the physical or the mechanical—is quite well understood as it is manifested above the glottis. It is not so well understood in the factors involving the trachea, the bronchi and their ramifications

The second group of causes—the biochemical—is frequently lost sight of altogether

As a preliminary to a brief consideration of the first group of causes, namely, that due to mechanical or physical complications, it is well to note the following

The anesthetic mixture of gases may be accurately measured, the available oxygen present may be adequate, but this accuracy is no more a guarantee of the ultimate adequate oxygenation of the patient's blood than is the presence of adequate oxygen always present in atmospheric air a guarantee against asphyxia in the presence of mechanical obstruction. We must not be deluded therefore, by the implied safety of mechanical devices which indicate oxygen percentages without, of course, any regard whatever for the factors which complicate the delivery of such gases into the blood stream. Unless the patient is the index governing the percentage mixture delivered to him, unnecessary anoxemia follows and increased morbidity and mortality will result. While there is a wide

margin of tolerance to varying degrees of anoxemia as far as mortality is concerned, postoperative sickness, increased bleeding, and muscular rigidity are all too common. Anesthetic devices delivering accurate mixture of gases are a convenience, they by no means guarantee a safe or efficient anesthesia

Let us now consider the mechanical factors which interfere with the proper oxygenation of the blood during anesthesia. We may consider these causes under two headings: respiratory and circulatory

I As regards the *respiratory* causes, we may note the following

Above the Glottis

- 1 Spasm and rigidity during induction
- 2 Engorgement of tissues as the immediate result of the anesthetic agent
- 3 Relaxation due to the anesthetic agent
- 4 Upper respiratory obstruction from nasal occlusion and laryngeal spasm as well as obesity and a plethoric state of the tissues
- 5 Obstruction from secretions, mucus, vomitus, blood

Below the Glottis

- 1 Spasm of the bronchioles due to asthma
- 2 Acute pulmonary inflammation partially obstructing the tubes
- 3 Fluid in the alveoli
- 4 Interstitial edema of the lining membranes
- 5 Reduced tidal volume
- 6 Atelectasis
- 7 Intrathoracic operations reducing the ventilating surface
- 8 Reduced partial pressure of oxygen by increased concentration of anesthetic

II *Circulatory*

- 1 Reduced rate or volume of the circulation
- 2 In infants congenital abnormalities of the heart and blood vessels
- 3 Congenital atelectasis
- 4 Central respiratory pressure
- 5 In operations involving the intracranial structures increased pressure due to abscess or tumors

As regards the biochemical causes of asphyxiation during anesthesia, the following may be noted as the most important:

1. Premedication by the basal anesthetics: morphine, hyocine, etc.
2. Artificial alkalosis with overventilation.
3. Reduced carbon dioxide concentration giving rise to the Bohr effect.
4. Anaphylactic reactions or idiosyncrasy due to the anesthetic.

In the first group of causes due to mechanical obstruction, the characteristic cyanosis of anoxemia is always apparent.

In the second group of causes, those due to biochemical effects, a true anoxemia as regards oxygen available for tissue use may be present in the absence of cyanosis. In other words, the patient with an apparently normal color may develop, unknown to the observer, a true asphyxiation whose existence will be apparent only through the rate, rhythm, and volume of the respiration.

Returning for a brief discussion of the foregoing causes of asphyxiation and reviewing the means available to meet these difficulties, it has been noted that a perfect device for administering anesthetic gases cannot guarantee the success of the anesthetic without a thorough understanding of the factors which may complicate the administration. This point should be strongly emphasized in laying down anesthetic routines for induction, maintenance and recovery. If anoxemia is not only undesirable but dangerous, the practice of inducing a patient with nitrous oxide to a point of jactitation and complete apnea, for the sake of speed, and the retention of a pure gas-oxygen sequence should not be tolerated. The reservation that such complete anoxemia can be immediately overcome by oxygen under pressure is by no means an invariable remedy for, granted the immediate biochemical effect of such insufflation, a patent airway instantly available must be presupposed.

Where difficulty exists, therefore, in inducing anesthesia with a gas-oxygen sequence, the use of a more powerful anesthetic, namely, ether, should be resorted to without hesitation. The addition of ether permits of a high concentration of oxygen which will produce sufficient oxygenation of the tissues, even in the face of a greatly reduced tidal volume.

It does not follow, however, as was formerly thought, that where the patient fails to respond promptly to the use of ether this anesthetic should be augmented by the use of a still more powerful anes-

thetic, chloroform. It is in precisely this situation that chloroform deaths are prone to occur. It may be said without hesitation that all patients may be completely anesthetized with ether in the presence of sufficient oxygen provided the necessary tidal volume is assured.

One of the greatest advances in anesthesia during the last two decades was the introduction of the pharyngeal tube or artificial airway. The introduction of this tube previously lubricated, with a free edge of sufficient gage to allow of a soft level, introduced with due respect for the structures which it must encounter, may be depended upon to bring about complete anesthesia.

In the presence of initial obstruction due to rigidity and to the engorgement of the tissues from anoxemia where such spasm will not permit of the introduction of an oral tube, a nasal tube, an improvised catheter, stomach or rectal tube, lubricated by the patient's saliva should be immediately passed along the floor of one nostril into the oropharynx. The prompt relief thus obtained may be augmented by the brief insufflation of oxygen and the resumption of the inhaler.

Upon the completion of induction and the disappearance of rigidity, the most common and annoying mechanical obstructions which must be faced are those due to the falling back of the tongue and the accumulation of secretions in the mouth and pharynx. An unprepared patient will not infrequently complicate his induction by reflex attempts to empty his stomach. Rapid inductions with a gas-ether sequence in which no premedication has been used are almost invariably accompanied by increased salivation. Small children in whom lymphoid tissue is present obstruct themselves promptly in this manner. Nasal and dental operations are frequently accompanied by bleeding which mechanically interferes with the freedom of the respiration. It is obvious that in the presence of such conditions an anesthetic machine devised to deliver a definite percentage of gases will fail to afford the oxygen required by these complications. Suction should always be available not only in the operating room but in the anesthetizing room where secretions accumulating during induction frequently hamper the anesthetic. One of the most convenient forms of suction for permanent installation is that afforded by the ordinary steam ejector which may be placed in any convenient steam circuit.

One of the most annoying forms of mechanical obstruction is that due to laryngeal spasm. Such spasm promptly interferes with the tidal volume and completely throws out any predetermined mixture. It is frequently difficult to locate the cause. Sudden ether concentration, sudden pain reflex, aspiration, or incorrect position of the head, should each be eliminated in turn. If gas-oxygen is being administered, oxygen should be increased and ether resorted to.

Mechanical obstructions below the glottis are commonly met with. One of the most frequent causes of such obstruction is asthma or chronic bronchitis. The spasm present and the reduced tidal volume as well as the restricted ventilating surface suggest the necessity of premedication and an anesthetic mixture with a high oxygen concentration. In asthma, the anesthetic actually affords a rational treatment for an attack. A high oxygen concentration implies the need of ether as the chief agent. The tendency of ether is to produce a dilatation of the airways through which dilatation the additional oxygen administered is more readily absorbed.

In the case of acute pulmonary inflammation the anesthetist is faced with a double problem. First, the traditional irritating effect of a vapor containing ether and, second, the tendency to atelectasis and increased pulmonary complications which may follow the use of sedatives sufficient to bring about anesthesia. The tendency to the accumulation of pulmonary secretions following the use of local anesthesia in these conditions, suggests that they must be used with care.

Chloroform, contra-indicated because of its recognized mortality under ordinary conditions, finds acceptance where gas-oxygen or ethylene-oxygen will not produce adequate control. It is the writer's experience in line with the reaction of the tuberculous patient that a low concentration (respirable) of ether in oxygen combined with nitrous oxide probably offers the best control of the anoxemia.

A very interesting distinction is to be made between secretions in the alveoli interfering with ventilation and inflammation of the alveolar epithelium. Fortunately, during anesthesia the interstitial edema of the alveolar walls is seldom seen. Fluid present in the alveolar spaces promptly absorbs the oxygen in the respired atmosphere and passes through

to the alveolar capillaries, provided a high concentration of oxygen is supplied. The likelihood of such absorption is greatly increased if the respired oxygen is placed under pressure. Even the 5- to 8-mm. pressure afforded by the bag of the inhaler is helpful.

The routine use of basal anesthetics and other pre-anesthetic medication is not infrequently followed by a reduced rate and small tidal volume. If to this is added respiratory obstruction from mechanical causes above the glottis, a low-grade and persistent anoxemia results. It has become the custom in nose and throat surgery to omit premedication for this reason. In abdominal work where a closed method may be used continuously, permitting of an autogenous CO₂ stimulation and an adequate supply of oxygen, little difficulty is experienced. However, the practice of overcoming such depression during induction by adding CO₂ to stimulate deeply the respiration thereby speeding up the induction, is fraught with the hazard that when such complete induction is obtained and the stimulating CO₂ is withdrawn, the respiratory center depressed by the anesthetic and overstimulated by the CO₂ may fail to respond.

In the presence of multiple or single atelectatic areas in one or both lungs, the resultant reduced respiratory surface will require oxygenation to a degree incompatible with the use of nitrous oxide as an anesthetizing agent. The same is true in the case of intrathoracic operations in which the patient must depend upon the absorptive area of a single lung. It is the practice in thoracic surgery to operate either with the incomplete anesthesia afforded by gas-oxygen with a high concentration of oxygen, or by an intratracheal anesthesia in which artificial obstruction to the respiration of the upper airway is mechanically overcome and through which facility ether-oxygen anesthesia may be used to advantage.

It is not uncommon to observe an increasing degree of anoxemia in the presence of a deepening of the anesthetic, especially where ether is used alone. The combination of mechanical obstruction plus the displacement of oxygen by the increased partial pressure of the ether is readily relieved by adding oxygen or reducing the ether tension allowing the patient to recover.

CIRCULATORY.—Cardiac disease in which the rate of the beat and volume delivered is materially reduced will show itself in cyanosis of the mucous membranes and skin. Valvular lesions are the most common cause of such conditions. It has been the writer's experience that the best cardiac stimulant kept within the limit beyond which it becomes a depressant, is ether-oxygen with CO_2 . Seriously decompensated cases are most safely approached by such technic. Such an approach is in contradistinction to the view formerly held in which it was attempted, by the use of chloroform, to reduce the rate of the heart beat and the strain brought about by the peripheral circulation. This approach was handicapped by the fact that the reduced respiratory excursion failed to provide the assistance to the pulmonary circulation which is constantly present in a free, deep respiration. Mechanical conveniences to overcome respiratory obstruction and the convenience of oxygen- CO_2 now renders ether the anesthetic of choice in preventing anoxemia in such cases.

In new-born infants one of the best proofs of the presence of a cardiac lesion or of a congenital abnormality of the large blood vessels in which the blood from the right ventricle is short-circuited into the general circulation, is the persistence of anoxemia in the presence of respired or insufflated oxygen.

Much work remains to be done in the field of congenital atelectasis. The presence of such atelectasis is always evidenced by a relative anoxemia which, however, disappears on the insufflation of oxygen to reappear once more when this treatment is withdrawn. The amount of pressure to be used in the intratracheal insufflation of such infants is usually limited to 25 mm. and its duration does not exceed five seconds. The effects produced by this insufflation are variable and depend upon the extent and the nature of the atelectasis.

In the case of central respiratory pressure in operations in the cranial cavity, or where medication has caused the cessation of the activity of this center, nothing remains but to support the circulation by the intracheal insufflation of oxygen until such time as the effects of the depression may be overcome or the circulation fails. In a recent case in which there was central respiratory paralysis owing to the presence of a cerebellar abscess, the circulation was maintained by such insufflation for a period

of fifteen hours, trephining being done in the course of this period without the necessity of any anesthetic agent.

PREMEDICATION.—The second group of causes comprises the biochemical, namely, premedication, artificial alkalosis, the Bohr effect, and anaphylaxis. The beneficial effects of premedication—reduced nervous tension, quiet induction, reduced amount of inhalation anesthesia during maintenance with increased ease of control—are frequently complicated by:

(a) Reduced rate and depth of the respiration.

(b) Narrow margin of safety where full relaxation is necessary.

(c) Reduced activity of the swallowing and cough reflexes following operation.

The ill effects of premedication above noted may be met during induction and during maintenance in surgery of the abdomen and extremities, for under these conditions rebreathing and CO_2 stimulation may be freely employed.

In surgery involving the nose and throat, however, induction is frequently difficult and the control of maintenance is lost owing to the reduced rate and depth of the respiration.

Of even more serious importance, since the cough and swallowing reflexes are depressed, is the aspiration of blood and vomitus which may take place during recovery following nose and throat operations or where the field is mechanically obstructed by nasal packs or sponges left in the tonsil fossae for purposes of hemostasis.

With a view to protecting the patient from these generally recognized hazards, the author has made it a practice to omit routine premedication before nose and throat operations. It is conceded that this technic increases the excitement during this period, but when this is balanced against the embarrassment caused by the depressed respiration during induction, and the danger of aspiration and asphyxial obstruction during recovery, it is felt that this difficulty must be accepted.

In order to reduce the danger of post-operative asphyxia from aspiration and obstruction, the author makes it a practice to place all patients on the side, with the head extended, immediately after operation, whether this be for a nose and throat or an abdominal operation. The patient remains in this position until his reflexes have been completely recovered.

ARTIFICIAL ALKALOSIS WITH OVER VENTILATION—The possible harmful effect of excessive preoperative alkalinization may be deduced from the following considerations

The normal rate and rhythm of the respiration are determined by the stability of the hydrogen ion concentration within the normal limits of 7.3 to 7.5 (Hydrogen ion concentration, pH of water is 0.0000001, seven decimal places referred to as 7). The normal pH of the circulation is between 7.3 and 7.5, below 7.3 is considered an acidosis, above 7.5 an alkalosis.)

This stability is also represented by the fraction $H_2CO_3/NaHCO_3$ in the proportion of 1/20.

An increase in the H_2CO_3 either through breaking down of the tissues or by the inhalation of CO_2 causes a $1+1/20$, resulting in dyspnea, until the excessive H_2CO_3 is reduced or the $NaHCO_3$ is increased. Yandell Henderson has shown that dogs placed in an atmosphere high in CO_2 in which their H_2CO_3 is raised $1+1/20$, will gradually become tolerant of this excess. If these dogs are now removed from the atmosphere high in CO_2 , their H_2CO_3 is lost more rapidly than the $NaHCO_3$. As a consequence of this disturbed ratio, the CO_2 available for the stimulation of the respiratory center is insufficient to bring about the necessary respiration and the dog dies of apnea.

The same condition may obtain in the child who is overalkalized and who may suddenly develop a reduced H_2CO_3 by overventilation, such as may occur by crying with the airway wide open in the presence of an open ether administration, by the stimulating effect of pain reflexes, and the total absence of rebreathing. A rapid respiration becoming more and more shallow in the presence of overventilation and with a background of prolonged alkalization, should be promptly recognized and rebreathing or CO_2 administered.

Furthermore it is to be noted that such a patient suffers asphyxiation or oxygen want without the usual phenomena of cyanosis. The reason for this situation is as follows:

REDUCED CO_2 CONCENTRATION GIVING RISE TO THE BOHR EFFECT—Oxyhemoglobin is an unstable compound. It yields its oxygen to the tissues with a varying degree of rapidity. The speed with which oxygen becomes available for use by the

tissues depends upon the concentration of CO_2 or the ratio of $H_2CO_3/NaHCO_3$, which is present in the circulation.

It is obvious, therefore, that a $1+1/20$ ratio, artificially established, either by overalkalization or by overventilation will result in a relatively stable hemoglobin. This hemoglobin, therefore, while carrying oxygen and giving to the blood its normal color, fails to give up its burden to the tissues. Clinically, we see a patient with a rapid, shallow, failing respiration, a small, running, thready pulse, a pale but pink skin and mucous membranes.

In view of this profound and serious biochemical disturbance which may result from overventilation or excessive use of the soda lime absorption technic, it is well to be prepared to meet this little recognized asphyxia occurring without cyanosis, by early and adequate oxygen CO_2 treatment.

ANAPHYLACTIC REACTION OR IDIOSYNCRASY DUE TO ANESTHESIA—Unusual reaction to anesthetic agents occurs not infrequently when local anesthetics are employed. Among the local anesthetics, cocaine is most to be feared.

The biochemical reactions are too complex for present discussion. The fact remains, however, that in the course of such an anesthetic the patient may suddenly lose consciousness, develop an imperceptible pulse, and cease to breathe.

On the assumption that the circulation while not discernible may still be functioning, the indications are to practice intra tracheal insufflation wherever relaxation of the upper airway permits this procedure.

In this connection it is well to bear in mind the danger of the use of adrenalin in conjunction with chloroform anesthesia. Such medication not infrequently precipitates a fatal ventricular fibrillation.

It has been suggested that the sudden, hitherto unexplainable deaths which have occurred during the early stages of a chloroform administration, in which the patient expressed grave anxiety concerning the experience which he was about to approach, may be explained through the sudden hyperfunctioning of the adrenals, known to take place under such conditions. All such cases presenting the symptoms of apparent death should have the benefit of immediate oxygen CO_2 therapy, by a technic best designed to meet the conditions.

The technic of relieving asphyxiation

occurring during anesthesia should include all the physical and chemical means at our disposal. The physical turn on the principle of securing a patent airway. The chemicals depend upon the use of oxygen- CO_2 for direct relief and the proper selection of premedication and of the anesthetic agent.

Since the proper choice of anesthetic agent and the use of oxygen- CO_2 has been repeatedly referred to in the foregoing, we may confine our attention to a consideration of the physical or mechanical means which we have at our disposal to insure the freedom of the airway.

Where abundant oxygen is used during induction, the early spasm and rigidity may be ignored provided the oxygenation of the tissues is adequate. A small tidal volume passing through a restricted airway, if carrying a high percentage of oxygen and a sufficient concentration of the anesthetic, will usually be followed by sufficient relaxation to permit of the separation of the teeth by the fingers. When this separation is sufficient to permit the introduction of an airway or pharyngeal tube, prompt relief is experienced. In the case of a severe spasm complicated with nasal obstruction occurring in a florid individual a marked and alarming cyanosis comes on very quickly. This may be relieved by passing a small tube lubricated with the patient's saliva along the floor of one nostril beyond the site of obstruction. Oxygen insufflated through this tube will immediately relieve the cyanosis and often permit a sufficient temporary relaxation to permit the introduction of a pharyngeal tube. The relaxation following complete anesthesia is best dealt with by the routine use of a pharyngeal tube. This tube should be constructed of material of heavy gage so that the edge may be rounded. It is well to lubricate the tube before intubation, one being careful that it is passed over the surface of the tongue and not against the frenum. Trauma frequently results in the hasty use of a light-gage, roughened tube introduced in the face of severe spasm of the masseter. Too large a tube will sometimes cause trauma of the fauces in a narrow pharynx.

Suction should always be available in every anesthetizing and operating room, particularly where no medication has been used, as in the case of little children and in adults in whom it has been withheld.

Suction should always be available for immediate use to control unexpected vomiting or hemorrhage. It is not sufficient that the equipment be available within a few minutes. It should actually be in operation with a sterilized suction tube attached. There is no excuse for not providing such protection as even the element of expense is largely done away with when steam is used as a source. A simple, powerful steam injector in any nearby steamline provides inexpensive and adequate suction for all types of work.

Laryngeal spasm is sometimes difficult to control but usually yields to a deepened anesthesia. While the use of the pharyngeal tube or airway is generally accepted, the extension of this convenience and life-saving technic down to and through the vocal cords, is not commonly practiced.

With a view to developing the simplest possible procedure to overcome respiratory obstruction above the trachea, thereby allowing the free respiration of the patient by overcoming the many causes of obstruction occurring during nose and throat work, an intratracheal inhalation tube was developed some seven years ago under the immediate direction of Chevalier Jackson. Great attention was directed to the avoidance of trauma to the glottic tissues. In order to remain within the safety limit as to size and shape as well as to consistency, the intratracheal section was made identical to the ordinary bronchoscope, permitting thereby the vast and varied experience of bronchoscopy to substantiate its safety. It is well recognized that glottic trauma in the ordinary bronchoscopy is negligible when practiced with ordinary care. If, to this margin of safety, is added the relaxed field offered by anesthesia and if the tube for this purpose is lubricated, the margin of trauma becomes certainly less than the dangers which one must face by the failure to intubate where indications are present.

The second point of importance was to practice a technic of intubation which was surgically clean and subject to the safety which direct vision alone will provide. The technic of exposure recommended by Chevalier Jackson again provided the ideal to be followed. The complications which the ambulatory anesthetist must face in the care of equipment was greatly reduced by the use of a simplified laryngoscope entirely serviceable for short exposures. This simple laryngoscope, is of great practical value and dependability.

The technic of laryngoscopy in the conscious patient under local anesthesia is technically difficult. The ease of this procedure is directly in proportion to the muscular relaxation brought about by anesthesia. A well-relaxed patient is ordinarily intubated with the greatest ease. A partially relaxed patient is much more difficult. The popularization of gas-oxygen for anesthesia with the least possible ether has produced a state of affairs where many anesthetists are no longer capable of producing a full and safe ether anesthesia with complete relaxation. Such a handicap by placing an undue resistance against the otherwise simple procedure of laryngoscopy has resulted in the popularization of blind intubation.

It seems hardly necessary to point out the trauma and the danger of infection when a blind technic is consistently followed, especially where an intratracheal tube passes through a nostril on its way to the glottis. However, the popularization of this technic because of its somewhat greater ease of manipulation demands that the dangers faced should be recognized.

The third consideration in the original preparation of the intratracheal inhalation tube was its consistency. The ideal to be achieved was the largest possible tube containing the thinnest possible wall; this wall to be made of a material which would not become soft and compressible. In the early periods of our experimental work, rubber tubes were used. These gradually became softened and were easily compressed by instruments and sponges pressing upon them. Such resultant collapse was, of course, fatal to the technic. Furthermore, it is difficult to understand the power of the glottic reflex unless one has frequently seen this in action. Such reflex may readily compress a softened rubber tube thereby obstructing the airway.

Lastly, it was found of great value to pass a suction catheter through the intratracheal tube to remove secretions which may have accumulated in the tracheal bronchial tree during induction or in the course of the anesthesia. The writer considers this feature one of the most important in this technic. A tube yielding the largest possible lumen and the thinnest possible wall which would at the same time prevent compression and provide flexibility, was finally secured by adopting a Penrose tubing to a tightly wound, non-corroding spring.

The writer has used this tube for the last six years. He has been repeatedly impressed with the consistency with which it provides the safety and the control desired. Irritation of the glottis and trachea has been conspicuous by its absence. Occasionally a soreness of the pharyngeal mucosa is complained of when the gauze packing used is not lubricated. In long cases some irritation of the trachea has resulted from contact with the tube. This may be reduced by moving the position of the tube during the course of the operation. Since the great majority of the patients intubated have been anesthetized for conditions of the nose and throat where the danger of aspiration was always present and the duration of the anesthesia was often determined by its efficiency, the writer feels that the complications referred to are much more than counterbalanced by the safety and the efficiency provided. As time goes on, his reaction is to use this tube more frequently instead of less frequently. He has never regretted intubating a patient but has frequently regretted a failure to do so. The actual clinical application of this technic may best be demonstrated by the motion picture which follows and which will conclude this paper.

CONCLUSIONS.—The prevention of asphyxia in anesthesia turns upon the control of two factors: the physical and the biochemical. The physical or mechanical occur above and below the glottis. The various causes of obstruction above the glottis are well recognized. Those below the glottis are not so well understood. The biochemical causes of asphyxiation are frequently lost sight of altogether.

It is pointed out that the most accurate measurement of the anesthetic is promptly thrown out in the face of obstructive complications. It is also pointed out that true asphyxia may also occur without cyanosis in the absence of adequate CO_2 in accordance with the effect described by Bohr. A brief reference to the effect of the hydrogen ion concentration upon the tidal volume of the respiration is made in which the stabilizing factor is shown to be the consistent maintenance of the proportion of H_2CO_3 to NaHCO_3 in the circulation.

The relief of asphyxiation during anesthesia is pointed out as being both chemical and physical. The chemical control is exercised through the correct choice of pre-

medication and anesthetic agent. The physical by the correct use of the pharyngeal tube as well as a safe and efficient intratracheal inhalation tube which should possess the qualifications of a correct diameter, widest possible lumen, combined

with thinnest possible wall intubated by direct vision.

Continuous experience of six years has demonstrated the safety and efficiency of this technic.

THE TREATMENT OF ASPHYXIA IN CLINICAL DISEASE, WITH ESPECIAL REFERENCE TO RECENT DEVELOPMENTS IN THE USE OF OXYGEN IN HEART DISEASE

ALVAN L. BARACH, M.D.

New York City

Asphyxia is a general term employed to designate a serious form of oxygen want. The author's concern is especially the diseases of the lungs and heart in the course of which an abnormally decreased tension of oxygen is present in the tissues. Last year he had the privilege of presenting clinical data concerning 376 oxygen-treated cases from a study made at the Presbyterian Hospital.¹ In this communication it is intended to state the more general views based on these results and the author's previous experience in oxygen therapy, and to indicate frankly wherein they differ from those of others. In addition, recent developments of the use of oxygen in cardiac disease will be reported.

In lobar pneumonia, lobular pneumonia, and postoperative bronchopneumonia the occurrence of oxygen want is a relatively frequent incidence. This condition should be promptly treated by the inhalation of an oxygen-enriched atmosphere. Our knowledge of the physiological consequences of acute oxygen want is sufficiently definite as to leave no question in the author's mind that harm of a progressively grave character is the result of untreated increasing anoxemia. The treatment should be instituted when signs of anoxia first appear; it should be continuous and should be maintained until the patient has given satisfactory evidence that the disease process in the lungs has sufficiently cleared so as to provide a relatively normal diffusion of oxygen through them. The indication for treatment is not only the existence of a cyanotic color to the nails or finger tips. A pulse unusually high in respect to the patient's age or temperature, excessive dyspnea, the presence of severe coughing, anemia, and marked restlessness are other signs that point to the advisa-

bility of employing oxygen. Bullowa,² has emphasized criteria other than cyanosis that are especially valuable in the treatment of colored patients.

The concentration of oxygen in the inspired air should be stipulated in any order for oxygen treatment, for the dosage employed is of real importance. In most instances, it seems best to employ 50 per cent oxygen in a well-ventilated tent or chamber. However, there are especially severe cases in which concentrations as high as 70 per cent may be used until the anoxic condition of the patient seems relieved. Very rich oxygen mixtures, such as those between 80 and 100 per cent, have repeatedly been shown to produce irritant inflammatory lesions in the lungs when used continuously for two to three days or more, but concentrations under 70 per cent have no such influence.³ Furthermore, there is no demonstrable *tendency* to produce edematous changes in the lungs when atmospheres containing less than 70 per cent oxygen are employed. The author has kept adult rabbits and infant rabbits, conceived and born in the oxygen chamber, continuously in a concentration of 60 per cent oxygen for three to four months without effect on the pulmonary epithelium. The use of oxygen concentrations between 90 and 100 per cent in human beings for long continuous periods is entirely unwarranted by present experimental data. The author has previously expressed his disagreement with the advice of Evans⁴ to employ these very high concentrations.

In the absence of a tent in which air movement, temperature and humidity control are available, it is best to use a nasal catheter, generally with a flow of 5 liters per minute. At this rate of administration, the patient will receive between 35 and 38

per cent oxygen in the inspired air, depending on the character of his pulmonary ventilation. With mouth breathing, the catheter in the nasopharynx is less useful. Under these circumstances, it would be advantageous to adopt the suggestion of Wineland and Waters⁵ to push the catheter downward into the posterior pharynx opposite the uvula. In a very limited experience with this latter procedure, it has been generally attended with a feeling of discomfort not complained of when the catheter is kept in the nasopharynx. It may frequently be possible to administer 7 to 8 liters oxygen through the catheter with a corresponding increase in the oxygen concentration of the inspired air, but these high rates of flow are apt to produce discomfort.

In most cases that present acute anoxemia, it is better to attempt to provide 50 per cent oxygen at the outset, allowing a margin of effectiveness beyond that just necessary to remove anoxemia. The measurement of the arterial oxygen saturation is too difficult to become standard for general clinical use. In the absence of a well-ventilated tent, the nasal catheter should be employed with a concentration approaching that of the tent where it is possible to do so. An oxygen tent that is not sufficiently comfortable and adequately equipped to provide hygienic atmospheric conditions in respect to air movement, temperature, and humidity had best not be used at all. In many cases the good results of effective oxygen therapy are obscured by the harmful effects of bad ventilation, or the patients themselves object to the treatment, which is then discarded.

The author also does not believe that the use of a mask is satisfactory. In his experience, it is generally productive of discomfort and furthermore, it is not possible to administer oxygen continuously and give the patient the frequent fluids he generally requires. The only three methods which therefore seem worthy of use are the oxygen chamber, a well-ventilated oxygen tent containing a mechanism for air movement, cooling, and dehumidification of the air, and the nasal catheter. The contribution of Wineland and Waters is of value especially for patients who breathe through their mouth; also their recommendations for higher flows of oxygen should be used in cases of severe anoxemia when a tent is not available and where the comfort of the patient is not disturbed thereby.

The value of oxygen treatment in acute respiratory disease is first of all a measurable relief of many of the symptoms of anoxemia. But one does not wholly comprehend the value of adequate oxygen treatment unless it is appreciated that the function of the vital systems of respiration and circulation may be sustained through the provision of an increased oxygen pressure in the blood and tissues in such a way as to afford the patient an opportunity of a greater length of life in which to overcome the toxemia of the disease. In a recent report the author⁶ presented case histories in which new evidence was advanced for the thesis that effective organ therapy is capable of prolonging life and in that way contributes additional chances for the ultimate recovery of markedly anoxic patients.

It now becomes necessary to consider the view that pneumonia is a pneumococcic atelectasis, that an undesirable lack of carbon dioxide exists in the tissues of the pneumonia patient, and that mixtures of 5 to 7 per cent carbon dioxide in oxygen should be more generally employed. In papers by Henderson, Haggard, Coryllos, and Birnbaum⁷ this attitude is upheld. The stimulation of deeper breathing is said to aid the clearing of the bronchi and thereby to tend to relieve the atelectasis, the Bohr effect of CO_2 is considered to promote an increased tension of oxygen in the tissues and the acid action of carbon dioxide has been said possibly to aid in resolution of the pneumonic exudate.

The stimulus for the use of mixtures of carbon dioxide and oxygen may be traced to the work of Henderson and Haggard⁸ in shock and anesthesia, in which they believed that a primary carbon dioxide deficiency was brought about by over ventilation during the excitement stage of anesthesia. Peters and Van Slyke⁹ have stated that such a hypothesis is untenable. The effects of excessive artificial respiration in producing conditions of shock, which Henderson and Haggard attributed to the resultant carbon dioxide deficiency, have been explained by the deAlmeidas¹⁰ as due, not to reduction of CO_2 tension or to increase of pH, but to cooling and to dehydration, a view adopted by Peters and Van Slyke. The application of these theories of Henderson and Haggard, to the use of 5 to 7 per cent CO_2 in pneumonia are thus open to question. In lobar pneumonia and in bronchopneumonia the

carbon dioxide dissociation curve is at times somewhat lowered, with a pH which has been found slightly on the acid or alkaline side but within the normal range in most instances (Barach, Means and Woodwell;¹¹ Hastings, Neill, Morgan and Binger.¹²) A number of cases have been treated with these high CO₂ mixtures but the absence of published studies of the CO₂ tension of the arterial blood has not made it possible to determine what actually happens to the blood of the individual being so treated. Clinically, observation of pneumonia patients exposed to these high CO₂ mixtures certainly has not given me the impression that they are in any way benefited by such a method.

Space does not permit to discuss in detail the view that lobar pneumonia has its origin in a plug of mucus obstructing a bronchus or that the acid action of CO₂ may possibly aid in the resolution of the pneumonic exudate except that it is necessary to say that the evidence presented for these views seems to the author quite inadequate upon which to base a proposal to substitute carbon dioxide and oxygen therapy instead of oxygen therapy, especially since the effects of doing so have not been adequately investigated by examination of the CO₂ tension and pH of the blood.

Not only in lobar pneumonia does it seem to be unnecessary and unwise to employ carbon dioxide in concentrations of 5 to 7 per cent, but also in postoperative pneumonia. This attitude is supported by the extensive study made at the Mayo Clinic on the use of oxygen therapy in postoperative pulmonary conditions by Judd, Boothby, and their collaborators.¹³ Judd summarized his experience as follows:

"There can be no question that the use of oxygen is a valuable aid in the immediate postoperative care of patients for whom surgical treatment has been carried out on account of some serious abdominal conditions. Among other beneficial effects, I believe that an important one is a tendency to prevent the accumulation of mucus in the respiratory tract and decrease the tendency to pulmonary edema. When breathing oxygen, the patient with shallow breathing is much more comfortable and has a better color than when he is breathing ordinary air. Comfort is a very important consideration in these cases. From our experience with the use of oxygen postoperatively, and particularly following operations in the upper part of the abdomen, we are convinced that it plays an important part in the convalescence. We frequently use it for forty-eight hours after any serious operation to prevent an anoxemia from developing. After the

oxygen tent is removed, the patient often asks to have oxygen again, stating that it adds greatly to his comfort. We feel that there be no question that the use of oxygen postoperatively has a definitely favorable effect on the prevention and treatment of pulmonary edema and congestion. In our opinion, we have materially reduced the incidence of postoperative pneumonia since using oxygen therapy freely following major surgical procedures. It is without question an important aid in the treatment of pneumonia."

The statement of Judd is quoted at length because it illustrates the value of oxygen therapy in accomplishing what has been claimed for the administration of high carbon dioxide concentrations in oxygen. It may be pointed out that the oxygen that frequently builds up concentrations of carbon dioxide of 1 per cent as it is ordinarily used, and occasionally as high as 1.5 or 2 per cent. These concentrations of CO₂ do not cause deep breathing as is produced by the inhalation of 5 to 7 per cent CO₂. In the author's experience, the presence of these small concentrations of CO₂ is associated with no evidence of harm or even discomfort. For over three years, at the Presbyterian Hospital, tents have been employed without soda-lime and reliance has been placed on a liberal flow of oxygen, 7 to 8 liters for maintenance and 15 liters per minute for purging when the flap of the tent has been opened, which is sufficient to cause adequate elimination of CO₂. If a concentration of 50 per cent oxygen is desired in a patient (not an untreated experimental subject), we have found it necessary to use such flows of oxygen as will (incidentally) keep the carbon dioxide concentration down to reasonable limits. An exception might be made in the case of postoperative thyroidectomy patients in whom an even larger flow of oxygen might be necessary to keep the CO₂ down, or in these instances soda-lime might be used in the tent. At all events, the small concentrations of carbon dioxide which are built up in oxygen tents and chambers appear in concentrations of 5 to 7 per cent CO₂ to stimulate the breathing noticeably.

In the recent pneumothorax treatment of pneumonia, collapse of the affected lung is frequently followed by a swift termination of the disease, if early cases without bacteremia are selected. It is apparent that this is a procedure quite opposite to the expansion of pulmonary air spaces and bronchial tubes which the inhalation of 5 to 7 per cent CO₂ concentrations is said to achieve. The author has seen the charts

of 8 patients and personally observed 2 cases treated at the hospital in which collapse of the affected lung was followed by crisis on the third or fourth day of the disease*. The pneumothorax, which was obviously responsible for the resolution of the disease, has an effect quite opposite to that of the inhalation of 5 to 7 per cent CO_2 .

Hanson and Calhoun made a report on 27 cases of lobar pneumonia treated with carbon dioxide and oxygen. The authors state that 4 normal persons who inhaled 95 per cent oxygen and 5 per cent carbon dioxide, using a mask, for periods of ten minutes, had the experience of feeling slightly faint at the end of the period but recovered quickly without any ill effects. The pneumonia patients were treated twice a day for ten minutes each time, no patient being selected whose illness exceeded three days. The authors concluded that early pneumonia could not be aborted with the technic they employed. The contrast between their negative results in this respect and that of pneumothorax in early cases is sufficiently striking as to make it additionally doubtful that forceful expansion of the bronchial pathways through the employment of these high CO_2 mixtures is desirable†.

The therapeutic effect of oxygen in chronic pulmonary conditions such as emphysema, pulmonary fibrosis, and the fibrosis of pulmonary tuberculosis has been investigated by Richards and Barach¹⁵. The results of treatment in these conditions are somewhat similar to our findings in chronic heart disease with the exception that more favorable responses are apparent in certain types of cardiac disorder after a shorter period of treatment than we obtain in end stage fibrotic pulmonary disease. In a forthcoming paper it was demonstrated that compensation in chronic congestive failure especially that associated with sclerotic conditions in the myocardium, or in the coronary artery, may be restored by oxygen therapy, even when all

other measures had failed. It may be said at the outset that oxygen therapy should not be employed to the exclusion of other measures in a clinical usage, the author's investigative attitude made it necessary at times to exclude other remedies when he employed it or to wait until other remedies had been found inadequate to restore compensation. Before turning wholeheartedly to the discussion of the use of oxygen in heart afflictions it may be mentioned that the chronic pulmonary patients have been also restored to a state of compensation in which ambulatory existence was possible, but in these patients the recurrence of the need for oxygen was more frequently present than in the patients with congestive failure due to an etiology exclusive of rheumatic fever. The benefit was in some cases quite lasting, as shall be seen presently.

In earlier publications Richards and the author¹⁶ pointed out that relief of dyspnea began in the first several hours of exposure to 50 per cent oxygen, that restlessness and insomnia were apt to be relieved in the first twenty-four hours, and that a diuresis generally began in the successfully treated cases between the third and the sixth day after oxygen treatment was begun. Further experience has confirmed these observations and has made it more clear that the cases of heart failure in whom there is evidence of an active rheumatic process are not apt to respond to oxygen therapy with a diuresis or with a recovery of compensation. What improvement does take place in the oxygen room or tent in the presence of 50 per cent oxygen is generally lost in the case of patients with active rheumatism on return to atmospheric air. However, in cases in which no evidence of active rheumatism is found or in which the basic cause of the heart failure is a myocardial fibrosis due to sclerotic changes in the coronary artery or to fibrosis in the cardiac muscle itself of undetermined etiology, the results of treatment may be to usher in quite promptly within several hours an increased consciousness of well-being, relief of dyspnea, restlessness and insomnia, and the development of diuresis from the third to the sixth day after onset of oxygen therapy. This diuresis continues until the patient is free from edema, in favorable cases in two to three weeks of treatment.

*The charts were observed as part of a study reported by Francis Blake, "Pneumothorax Treatment of Lobar Pneumonia," at the Association of American Physicians, May 2, 1934.

†In a recent English communication by Hilton further doubt concerning carbon dioxide therapy is expressed by the author's statement that, "The practical conclusion of this paper is that in the absence of respiratory failure as evidenced by shallow breathing the clinical effects of CO_2 administration in air are not sufficiently demonstrated by these observations to warrant its routine use in lobar pneumonia."—Hilton R., *Brit Med Jour* 1, 418, 1934.

If oxygen therapy is withdrawn before completion of diuresis, there is a real danger of re-accumulation of edema.

There is first noticed in the case of congestive heart failure admitted to the hospital a greater intake of fluids than an output of urine, if the patient is still decompensated. Three to six days after oxygen treatment is begun, a reversal of the trend takes place, *i. e.*, a greater output of urine than intake of fluids. The concentration of oxygen is maintained at the level of 50 per cent, until in the course of two or three weeks, it is observed not only that there is no longer any clinical edema but also that the intake of fluids becomes again greater than the output of urine. It is then likely that diuresis is approximately complete. The oxygen concentration of the tent may then be gradually lowered in the course of two or three days to 25 or 30 per cent and the tent removed. Frequently, the nasal catheter is used to accomplish a more gradual tapering-off process.

In favorable cases, the patient continues to gain strength and returns home capable of ambulatory activity.

Richards and the author have also been interested in the treatment of patients with cardiac insufficiency before a complete breakdown of compensation takes place. Our information on this subject is still too meager to lay down any general principles. However, in one patient, a colored man of 62 years who had a myocardial fibrosis and a two- and one-half-year history of increasing cardiac insufficiency, oxygen treatment for three weeks was provided before the stage of complete breakdown. At that time, he could not walk half a block before he had to stop because of dyspnea. At the end of oxygen treatment he was gotten up progressively on the ward and returned home. He was able to walk one to two miles at a time each day without dyspnea, and remained in good condition for one year, when a cold temporarily reduced his compensation. He is still in relatively good condition, one and one-half years later.

In these cases the most characteristic occurrence is a marked increase in the CO_2 content of the arterial blood, which may rise 50 per cent above the pre-oxygen treatment level and in the chronic pulmonary cases 100 per cent above the carbon dioxide content without oxygen. This elevation of the amount of CO_2 in the arterial blood is not dependent on the inhalation

of the small amount of CO_2 present in the tent and the chamber. The author has kept dementia praecox patients for two and a half months in 50 per cent oxygen with 3 per cent CO_2 and occasionally 4 per cent CO_2 , without any real effect on the CO_2 content of arterial blood.¹⁷ The increased amount of CO_2 in the blood is also not an evidence of a carbon dioxide acidosis, as the pH is normal. Without attempting fully to explain this phenomenon it can be pointed out that a higher tension of CO_2 in the blood makes for a more rapid elimination of CO_2 into the alveolar air, and a larger excretion of CO_2 per unit of air breathed. When the pulmonary ventilation is reduced, because of the provision of the increased oxygen tension in the blood and tissues, an apparently adaptive mechanism takes place, *i. e.*, the organism elevates the level of CO_2 in the blood, since at the higher levels it can eliminate carbon dioxide more efficiently. The expired air of the patient may thus contain 7 to 8 per cent or even higher concentrations of CO_2 , demonstrating a remarkable capacity of the organism to get rid of carbon dioxide, even through congested, edematous or fibrotic lung tissues. If the want of oxygen is overcome, the lung may eliminate per unit of breathing more than twice its customary amount of carbon dioxide at a normal hydrogen ion concentration. Previous investigation¹⁸ which emphasized that a carbon dioxide acidosis was responsible for cardiac dyspnea, as well as those which were negligent of the factor of anoxemia¹⁹ appear to be unsupported by the results the author has obtained. Other workers, such as Beddard and Pembrey,²⁰ Porges,²¹ Campbell and Poulton,²² grasped more correctly the importance of the anoxemic factor, which our studies of the ease of disposal of CO_2 in the presence of effective oxygen therapy tends to confirm.

The primary difficulty then in disturbance of cardiac and pulmonary function is the presence of an inadequate tension of oxygen in the tissues. The author does not mean to exclude mechanical factors such as the increased weight of passively congested lungs or restricted volume capacity of the lungs but to focus attention on the purpose of the respiratory system to deliver O_2 and eliminate CO_2 , and to point out that the disturbed function which makes for dyspnea is difficulty in delivering an adequate supply of oxygen and not

in eliminating an adequate amount of CO_2 . The provision of oxygen in passive congestive failure with anoxia often acts like a specific remedy, steadily overcoming the symptoms and the signs of cardiac insufficiency. Withdrawal of oxygen before a state of compensation has been achieved provokes a sharp and at times a severe breakdown in the obvious functions of both respiration and circulation. The secondary function of these symptoms, the elimination of CO_2 , is, however, accomplished promptly when the needs of the organism for oxygen are met. The statements that refer to the difficulty of getting rid of CO_2 through edematous or damaged lungs must now be viewed as theoretical assumptions not borne out by the fact that damaged lungs even in the presence of heart disease can afford an outlet to twice the customary amount of carbon dioxide per unit of air breathed. This is achieved through the maintenance as long as it is required, of a high arterial CO_2 content.

The use of high concentration of carbon dioxide is productive of acute discomfort in these patients, dyspnea of such a character as to make it intolerable.^{23, 24} It should be mentioned that there is no evidence that definite CO_2 deficiency takes place as a result of overventilation in the dyspnea of heart disease. At times the pH turns slightly in the direction of alkalosis, but more often it is normal or within a relatively normal range. Our results show, moreover, that the body is fully capable of conserving its carbon dioxide if its demands for oxygen are met, as exemplified by one patient with chronic pulmonary disease whose arterial carbon dioxide content rose to a height of 132 vol per cent. It may be that small concentrations of CO_2 , such as 1 and 2 per cent in the presence of 50 per cent oxygen may enhance the effectiveness of oxygen by increasing the movement of oxygen from the blood to the tissues (the Bohr effect). The author's experience with higher concentrations of CO_2 is that discomfort and increased dyspnea are produced. The enormous building up of carbon dioxide in the arterial blood as a result of the provision of oxygen therapy, is a demonstration of the capacity of the patient in dyspneic conditions to maintain a high CO_2 level if his primary difficulty, the lack of oxygen, is met.

In acute coronary thrombosis Levy and the author²⁵ have observed additional pa-

tients in whom the inhalation of 50 per cent oxygen aided the function of the heart damaged by anoxemia and shock, in this way augmenting the chances of ultimate recovery. The author has also seen additional cases of chronic anginal pain in which the inhalation of oxygen relieved the patients of pain during the period of residence in the oxygen atmosphere. Also, at this point the author must express his doubt of the efficacy of high CO_2 concentrations in the treatment of angina pectoris and voice his disagreement with the statement²⁶ that 'For the treatment of angina pectoris and for use on patients after anesthesia and surgical operations, oxygen is unnecessary'. The extension of carbon dioxide therapy from its employment during anesthesia to clinical disease characterized by oxygen want must be squarely faced by both physiologists and clinicians. Both from the standpoint of theoretical evidence and actual experience, a halt should be called to the use of 5 to 7 per cent carbon dioxide, except in those conditions in which there is evidence of an insensitive respiratory center, such as drowning, carbon monoxide poisoning, drug poisoning, and so forth. It should also be admitted that the efficacy of CO_2 therapy in carbon monoxide poisoning is not merely due to stimulation of ventilation but, as Stadie and Martin²⁷ pointed out, to the displacement of CO by CO_2 . The author wishes to acknowledge the great value of the work of Henderson and Haggard in emphasizing the usefulness of CO_2 in conditions where a depressed state of the breathing is apparent, such as carbon monoxide poisoning but its extension by them and others following their foot steps to pulmonary and cardiac illnesses which are already characterized by dyspnea seems to us unwarranted.

In atelectasis of the lungs of the newborn, the use of 5 per cent CO_2 to cause expansion of the lungs is undoubtedly valuable, as Henderson⁸ states especially if obstructive lesions have been removed (Flagg²⁰). High CO_2 mixtures should be used only intermittently in these conditions, sufficient to stimulate breathing, and reliance should be placed upon the provision of a 50 per cent oxygen environment to maintain an adequate oxygen supply until the lungs expand sufficiently to do without this oxygen. If the breathing has been instituted with 5 or 10 per cent CO_2 the inhalation of 50 per cent oxygen may be

sufficient from then on, or it may seem wise to give further short inhalations of carbon dioxide. It is generally unnecessary to keep the child in a continuous environment of 5 to 7 per cent CO_2 . There is often no indication to continue high carbon dioxide concentrations, especially since oxygen with 2 or 3 per cent CO_2 will frequently maintain the pulmonary function adequately without it.

Finally the use of oxygen in connection with thyroidectomy for various forms of heart disease, as recommended by Blumgart, Levine, and Berlin³⁰ should be mentioned. It is not the purpose of this paper to discuss the results of thyroidectomy. Observations by Richards, Caughey, Parsons, Barach, and others are being made in an attempt to evaluate this procedure. However, the program of treating these patients may be mentioned. It consists of a period of preoperative oxygen treatment designed to put the patient in the best possible condition. If he has cardiac insufficiency, he is placed in the oxygen chamber for 2 or 3 weeks, or until he shows evidence of compensation. Even if a state of compensation is present, four to five days in the oxygen room are provided with the idea that an additional support to the cardiac muscle is thereby achieved. The operation is performed with the patient receiving 5 liters of oxygen per minute by nasal catheter, following which he is returned to the oxygen room for approximately five days, when the oxygen is gradually lowered during the course of two days and the patient returned to atmospheric air. The theoretical basis for this procedure rests on the results of Richards and the author¹⁰ in which the effects of oxygen-enriched atmospheres on circulatory function have been demonstrated. The mortality of cardiac patients exposed to operation, including those other than thyroidectomy, has been greater than that of the noncardiac. We are hopeful that we have developed a method which will materially reduce the mortality of cardiac patients exposed to serious operation. In the early part of this paper Judd's experience was quoted, in which he believed that the operative surgical mortality was reduced by placing patients in an oxygen environment immediately after operation. Our proposal is an extension of this principle to the actual period of operation, and also to a preoperative period during which the reserve or

the function of the heart may be improved. The postoperative course in the 6 cases which have been done by Dr. Parsons has been so exceptionally smooth that we have been led to the belief that anoxic shock has been averted, and that the hazard of the operation has been thereby reduced.

SUMMARY

Observation of the use of effective concentrations of oxygen in lobar pneumonia and bronchopneumonia over a period of fourteen years justifies the view that (1) the symptoms of oxygen want are frequently thereby relieved, and (2) that in some cases the function of the lungs is sustained by the provisions of an increased oxygen supply. Both these effects increase the opportunity for ultimate recovery of the anoxic patients suffering from acute respiratory disturbances.

The method by which oxygen is administered is of great importance. A well-ventilated oxygen chamber or tent seems preferable to other methods. A tent which is inadequately equipped with a mechanism for air motion, reduction of temperature and humidity of the enclosed atmosphere should be abandoned in favor of the nasal catheter which, although less desirable than a well-ventilated tent, is to be preferred to one in which hygienic conditions of atmosphere control cannot be maintained. The nasal catheter may be employed with moderate effectiveness.

Recommendations in the literature for a more extensive use of carbon dioxide in concentrations of 5 to 7 per cent in lobar or bronchopneumonia appear to the author unsupported by the theoretical and clinical evidence now available. This type of therapy, in the author's opinion, should be employed in the conditions in which depressed respiration is present, such as CO poisoning, submersion, and so forth, in which its value has been fully substantiated.

The effectiveness of oxygen therapy in cases of congestive heart failure, its capacity to accomplish a restoration of compensation, has been demonstrated by Richards and the author. It has been found especially marked in those patients who are free from an active rheumatic process. Patients with degenerative forms of heart disease characterized by myocardial fibrosis or patients whose myocardial failure is secondary to coronary arteriosclerosis have shown great improvement as a result of oxygen treatment for two to four weeks.

Its influence in chronic pulmonary conditions such as emphysema, pulmonary fibrosis, and the fibrosis due to end-stage tuberculosis is similar, with the exception that longer treatment is necessary and recurrence of oxygen treatment more frequently needed.

The use of oxygen in acute coronary thrombosis has been further observed by Levy and the author with a confirmation of the view that oxygen treatment may be of great importance in this condition because of its sustaining influence on cardiac muscle function.

Oxygen has been used in the course of an investigation of the influence of thyroidectomy in various forms of heart disease. A preoperative period of oxygen treatment was instituted to obtain the highest degree of compensation possible before operation. Oxygen was administered during the operation. A postoperative period of oxygen treatment was employed to avert the consequences of abrupt anoxemia. The favorable postoperative appearance of the 6 patients so treated suggests the use of a similar procedure in cardiac patients exposed to other operations.

Evidence is presented which indicates that oxygen want plays a critical rôle in the causation of cardiac dyspnea and the dyspnea of chronic pulmonary disease. The relief of dyspnea and the restoration of compensation in these conditions may be accomplished in selected cases by appropriate oxygen treatment. In these cases an elimination of CO_2 as high as twice the normal concentration suggests that there is no inherent difficulty in passing CO_2 through the lungs, even in the congested, edematous, or fibrotic state.

ABSTRACT OF DISCUSSION

DR. JOHN H EVANS Dr Barach is entitled not only to the thanks but also to the sympathy of the medical profession. Thanks are due him for the strenuous efforts he has made during the past several years to find out the therapeutic value of oxygen. He is deserving of sympathy because he has been working under the self-inflicted handicap of limited dosage.

As a consequence, he has been forced to stand helplessly by and see many of his patients die of asphyxia which his dosage of 40 to 60 per cent oxygen was unable to correct.

The dosage of 40 to 60 per cent oxygen has been arbitrarily fixed by conscientious laboratory workers who conceived the ingenious but erroneous idea that the requirements of a patient suffering from asphyxia could be accurately measured by the tolerance of a healthy animal to oxygen.

They concluded from their experiments that no more than 60 per cent should ever be administered continuously to a patient suffering from anoxemia. If this percentage failed to restore the blood oxygen to normal, that was the patient's hard luck.

Although they found that normal rabbits could safely inhale 60 per cent oxygen for as long as four months they decided 40 per cent was as high a percentage as should be given mild cases of asphyxia. It has always been a mystery to me why the proven safe dose of 60 per cent should be reduced exactly 33 1/3 per cent. It was low enough before this bargain day reduction,

Oxygen is the only therapy which is handicapped by arbitrarily fixed dosage. In all other fields there is no limit placed upon the dose, enough being given to produce the desired results. The effect that the dose might have on normal persons is never taken into consideration. Often it is so large that it would be harmful or even fatal if given to a person in whom the treatment was not indicated.

The purpose of oxygen therapy in cases of anoxemia should be the restoration of normal blood oxygen. If it falls short of this objective, it cannot be considered successful. That 40 to 60 per cent oxygen is not capable of accomplishing this most desirable result in all cases is evidenced by published reports on its use.

In analyzing, for example, Dr. Barach's 1929 report of 100 cases of pneumonia we find that these percentages were successful in only 51 per cent of cases. Among the 49 per cent of failures were 36 cases in which the blood oxygen was from 11 to 16 per cent below the normal level and in 9 cases the failure was so great, namely, 16 to 21 per cent below, that death was almost certain to result from the uncorrected asphyxia. All of the 9 died.

Barcroft has shown that even a reduction of 8 per cent in the normal blood oxygen is followed by serious symptoms.

In view of this high percentage of failures it would seem that Dr. Barach is too optimistic when he states that 40 to 60 per cent oxygen restores the arterial blood oxygen of anoxic patients "to or near the normal value."

I hope that Dr. Barach will explain why normal animals were chosen as the criterion to measure dosage.

If the experiments had been carried out on animals suffering from asphyxia, I am sure that the percentage finally agreed upon would have been much higher. I base this statement on deductions drawn from a series of over 400 cases of asphyxia to whom we have administered 80 to 100 per cent oxygen.

The asphyxia in these cases was associated with pneumonia, cardiac decompensation, pulmonary emboli, coronary thrombosis, fibrosis of the lung, asthma, respiratory failure in infantile paralysis, postoperative anoxemias, and carbon monoxide poisoning.

The great majority of these cases were given 100 per cent oxygen by means of the face mask or nasal inhaler. Many of them inhaled the oxygen for from several days to as long as four weeks with as little interruption in the treatment as possible. The tests made when the nasal inhaler or face mask were used invariably showed the oxygen percentage to be above 90.

We have had several patients who developed cyanosis while inhaling 40 to 60 per cent oxygen given by the tent method. The cyanosis disappeared as soon as 100 per cent oxygen was administered with the mask. This was followed by an improvement in the patients' general condition.

Our best results have been obtained with the oxygen as near as possible to 100 per cent. This applies to the mild as well as to the severe cases of anoxemia.

When we are called to administer oxygen on the first day of a pneumonia we now give 100 per cent continuously throughout the course of the disease regardless of whether cyanosis is present or not. We find that there is increased comfort for the patient and in some cases it

seems that the course of the pneumonia is shortened or even aborted.

We have found that 100 per cent oxygen is a marked respiratory sedative, greatly reducing the cough or abolishing it altogether. There has been no evidence that it was irritating or that it was harmful in any way even when given continuously for long periods of time.

It has now been several years since Dr. Sayers demonstrated that 100 per cent oxygen could be safely inhaled by normal animals for at least 16 hours a day for at least 50 consecutive days. Inasmuch as Dr. Sayers has met the requirement of selecting normal animals for his experiment, I cannot understand why Dr. Barach does not take advantage of the information thus gained and permit all of his patients to enjoy a pink color with normal blood oxygen for at least 16 hours a day.

It has been unfortunate for the asphyxiated patient that reports have been so widely circulated branding 80 to 100 per cent oxygen as a poison and a respiratory irritant.

The diabetic, on the other hand, has been more fortunate as the death-producing effects of insulin have been screened by the term "reaction" and there has been no one in high authority to curtail the dosage. Many times the dose that would prove fatal to a person with normal blood sugar is not infrequently given to the diabetic patient. With insulin, the good old-fashioned rule of therapeutics has been allowed to hold sway, namely, to govern the dose by the needs of the patient. Enough is given to bring the blood sugar down to the normal range regardless of the number of units required or its effects upon a healthy animal or person.

In applying oxygen therapy to cases of asphyxia the same principle of dosage should be employed, namely, to give to restore the blood oxygen to normal. If this cannot be accomplished by inhaling 100 per cent oxygen, which very rarely happens, it may be advisable to administer it subcutaneously.

The ability of oxygen to reduce the heart and respiratory rates increases as the percentage of oxygen is increased. Hence the advisability of administering 100 per cent in all cases of pneumonia and cardiac decompensation, even though the cyanosis is abolished with lesser percentages.

When 100 per cent oxygen is administered continuously to the asphyxiated patient the effects are quite different to those produced in normal animals in which oxygen therapy is not indicated.

Instead of being a death producer it is often a life saver; instead of being a pulmonary irritant it is an excellent sedative; instead of producing edema of the lungs, it is beneficial for this condition, either reducing it or abolishing it altogether; instead of causing a pneumonia it is helpful in warding it off and is the best therapeutic agent we have for an already existing pneumonia.

DR. BARACH: The argument of Dr. Evans that investigations of the effect of pure oxygen in animals applies only to normal lungs and would therefore not apply to diseased lungs seems fallacious to me. The pneumonia patient may have only one or two lobes involved, and the rest of his lungs normal. There is every reason to believe that pure oxygen administered for two or more days would cause pulmonary irritation and edema in these normal lungs. Dr. Evans believes he had given pure oxygen continuously

for days without harm. It is difficult to administer pure oxygen continuously with a mask and at the same time provide medicine, food and fluids. From the work of Sayres one would be justified in concluding that even these very high oxygen concentrations could be borne 16 hours out of 24 without apparent harm.

Dr Evans' criticism of my early results employing 40 per cent oxygen reveals that in some of the cases the arterial oxygen saturation was not elevated to the normal level. In some of

them the passage of blood through unventilated lung might have made it impossible to raise the oxygen concentration entirely to the range of normal. In others however it is probable that the use of 60 per cent oxygen would have obtained a better result. I would consider it safe to use even higher concentrations of oxygen for a matter of some hours but I believe it dangerous to employ continuously concentrations of over 70 per cent for any period over two days.

THE LINGUAL DEATH ZONE IN ASPHYXIA

CHARLES R. JACKSON, M.D. and CHARLES E. JACKSON, M.D.

Philadelphia, Pa.

Death from asphyxia means death from want of oxygen and carbon dioxide in the tissues. The only practical way to get these gases permeated throughout the tissues is through the arteries. The question then is how to get these gases into the blood. Some day we may be able to put them directly into the circulating streams with a syringe but at the present time the only practical method is the normal way, via the lungs. We must, then, pipe the gases down into the tracheobronchial tree. It is seen at once that the essential thing is to keep these pipes open. The passageway down to the tracheobronchial tree is just as vital to the patient in impending asphyxia as is the tube that pipes air down to the diver when he is under water.

LINGUAL CHECK-VALVE ACTION IN THE DEATH ZONE—Though the dropping back of the tongue is a well known danger, it does not seem to be realized that the obstruction is of the *check valve* type. Worst of all is the fact that the check valve is set against ingress of air. Air and gases in the lungs may get out, but no air can get in.

The greatest menace to the patient in danger of death by asphyxia is the *lingual check valve*. Included in this *death zone* are two anatomical elements, namely, the pharynx which forms a funnel, and the tongue which on dropping back fills that funnel. The funnel forms a valve seat and the tongue forms a flapper, like the flapper of a check valve. The tongue is heavy and it is not held in place by any ligament, its only support is the muscles. In all forms of profound unconsciousness the muscles relax and the tongue has a strong tendency to go backward by gravity, when it does so, it shuts off completely

the air entrance into the larynx. This constitutes the death zone.

Fundamental then to all efforts to avert impending death by asphyxia is *elimination of the lingual check valve*.

HOW ARTIFICIAL RESPIRATION MAY KILL THE PATIENT—It does not seem generally to be realized that when the tongue drops back into the pharynx, it constitutes a check valve preventing the ingress of air but permitting the forcing out of air from the lung. Therefore when the attempt is made to use artificial respiration without first seeing that the tongue is drawn forward, the pressure on the chest walls will force the air out of the lung, but the inspiratory phase, expanding the thorax to draw in air, is unsuccessful because the air intake through the larynx is occluded by the dropping back of the tongue. This forcing out of air with the inability to take in any air results promptly in bilateral pulmonary atelectasis and immediate death.

KINDS OF ASPHYXIAL DEATHS FROM THE LINGUAL CHECK VALVE—We have in general two classes of cases in which the death zone should be considered. (1) Those in which the primary obstruction causing the asphyxia is located in the death zone for instance a tumor, cancer, foreign body, garroting, suicidal hanging, the baby who has never yet breathed (asphyxia neonatorum). It also often occurs in the course of administration of chloroform and ether and other inhaled anesthetics and some of the poisons. (2) Those cases in which there is apnea from the effect of gases, electric shock, and other general causes. The death zone comes in as a secondary factor and will

assist in killing the patient if it is not properly dealt with and eliminated at the start *before any attempt is made at artificial respiration*.

LINGUAL CHECK VALVE IN SLEEP.—The only reason why we do not all die in our sleep is that we waken before we asphyxiate. Just as soon as the tongue drops back against the posterior wall and fills the pharynx, closing off the upper laryngeal orifice we waken and with resumption of partial consciousness the tongue goes back to its proper place. When, however, due to any cause such as alcohol, drugs, etc., the sleep is unusually profound, the patient may not waken. Undoubtedly many of the cases of death attributed to cardiac failure in alcoholism are really due

the chest is compressed before the tongue is drawn out. Of course, experienced anesthetists usually elevate the tongue by raising the jaws and no drawing out of the tongue is necessary. Intratracheal insufflation anesthesia, obviously, overcomes all difficulties with the death zone. Dr. Paluel J. Flagg has introduced a method of insertion of a closely fitting rubber tube in the larynx giving the anesthetist a complete airway to the lungs with which nothing can interfere. This is a most perfect method from the mechanical point of view and in clinical practice it is daily yielding wonderful results.

In *apnea* there is primarily no obstruction; but as soon as unconsciousness supervenes the lingual check-valve action will kill the patient if it is not eliminated.

Fig. 1.—The Death Zone. *A*, Normal position of the tongue. *B*, In the relaxation of impending asphyxia the tongue drops backward obstructing the ingress of air. If artificial respiration is started with the tongue in this position, the patient will be killed by the pumping of air out of the lung on the compression stroke and no air can enter on the inspiratory stroke; the tongue forms a check valve permitting passage in one direction only. For artificial respiration the tongue should be drawn forward with tongue forceps or the

fingers covered with a handkerchief or gauze; but the best way to open up this death zone is with the direct laryngoscope as shown at *C*. Oxygen and carbon dioxide can then be insufflated. Every ambulance and every accident ward should be equipped with a direct laryngoscope, a 5 mm. bronchoscope, and a tank of oxygen with 5 per cent carbon dioxide. An aspirator for secretions would be useful, but in an emergency gauze or even a handkerchief can be used to clear secretions out of the death zone.

to asphyxia, the result of the lingual check-valve action above described.

SUCTION IN THE DROPPING BACKWARD OF THE TONGUE.—In addition to gravity, suction is a factor in the death zone. Suction may be due to absorption of air but chiefly to inspiratory movements. It is cumulative in the sense that the farther back the tongue goes the greater the power of suction becomes, because of a tighter fit.

The *death rattle* is sometimes caused by the bubbling of secretions; more often it is the final flapping of the lingual check valve. Dropping back of the tongue is the final stage in the death of anyone dying from any cause in the recumbent position.

THE DEATH ZONE IN ANESTHESIA.—Keeping the death zone clear is so well known to all anesthetists that nothing need be said beyond calling their attention to the check-valve action by which bilateral atelectasis and asphyxia is completed if

RHYTHMIC TRACTION ON THE TONGUE.—It is in many ways unfortunate that the rhythmic traction on the tongue was proposed in the way it was. It may be true, and it probably is true, that rhythmic traction on the tongue has a tendency to stimulate respiration; the unfortunate thing is that attention has been drawn away from the entirely different reason for drawing the tongue outward, namely, the elimination of the death zone and its check valve action, which require that the tongue be drawn out and held out.

THE DEATH ZONE IN ARTIFICIAL RESPIRATION.—One of the chief reasons for a greater success of the prone-pressure method as compared to the Sylvester and other early methods is that the position with the face turned downward, even though somewhat sidewise, permits the tongue to drop away from the posterior pharyngeal wall and from the orifice of the larynx so as to eliminate the death

zone Of course, it is always stated in the instructions for the use of any method of artificial respiration that the mouth must be cleared of secretions, and the tongue must be drawn forward In practical work, however, only too often, the tongue is neglected either altogether or until the patient has been killed by the compression stroke which has emptied the lungs and left them in a collapsed state because the check valve of the death zone has prevented any air entering on the inspiratory stroke

THE PULMOTOR AND OTHER AIR PRESSURE METHODS—Unless great care is taken to draw the tongue forward and keep it forward, the effect of the pulmotor and similar pressure methods is to force the tongue backward and to increase the certainty of death by the lingual check valve mechanism Of course, this does not apply to pressure methods that are used in combination with the laryngoscope to open the airway

THE LARYNGOSCOPIC METHOD OF ELIMINATION OF THE DEATH ZONE—Of all methods of eliminating the death zone and resuscitation of the patient the best is the clearing of the airway with the direct laryngoscope The spatular end of the instrument is inserted back of the tongue and then the patient's head is raised by a lifting motion of the instrument in the direction of the darts (Fig 1, C) The technic is quite simple in the limp condition in which a patient always is when asphyxia is impending The chief thing to remember is that the patient's head must be suspended on the spatula as shown in the illustration The operator can then see the larynx, see that there is no obstruction in it, and can insert a bronchoscope for clearing out of the secretions and for the insufflation of oxygen with carbon dioxide mixture right down to the air vesicles This is the cleanest, quickest, most logical and mechanically the soundest way of forcing the vitally necessary gases down to where they can be taken up by the pulmonary vessels and distributed to the tissues

SUMMARY

- 1 Fundamental to all efforts to avoid impending asphyxia is the elimination of the deadly lingual check valve
- 2 The best way to eliminate the lingual check valve is by direct laryngoscopy (Fig 1, A) With the patient on his back the

direct laryngoscope is inserted backward until it touches the back wall beyond the tongue Then by a lifting motion the head of the patient is hung up on the cylindric part of the instrument This brings the tongue away from the back wall of the throat so as to allow air to get down back of the tongue into the larynx This constitutes the elimination of the deadly lingual check valve

3 The bronchoscope is introduced into the larynx and trachea through the laryngoscope The oxygen tube should not be connected to the bronchoscope until after the oxygen has been turned on and the pressure regulated Otherwise a heavy discharge of oxygen might occur

4 Aspiration of secretions through the laryngoscope or bronchoscope prevents the patient drowning in his own secretions

5 If the means for doing direct laryngoscopy are not at hand, artificial respiration is the alternative The best method of using it is known as the prone pressure method, but regardless of the method used, it is necessary always to remember the deadly lingual check valve, eliminate it by seeing that the tongue is drawn out and held out

6 The necessary equipment for the prevention of asphyxial death that should be in every ambulance and every accident ward is as follows

- 1 direct laryngoscope,
- 1 bronchoscope, 5 mm by 30 cm of full lumen aspirating pattern
- 1 tank filled with oxygen containing a 5 per cent mixture of carbon dioxide,
- 1 piece rubber tubing, about 4 ft long attached to tank outlet

ABSTRACT OF DISCUSSION

DR E T BUTLER Elmira, N Y Dr Jackson has aptly described the crossroads of the alimentary and respiratory tracts Crossroads are frequent scenes of accidents and it is no exaggeration to state that the anatomical crossroads in question are responsible for many fatal mishaps

In addition to the tongue other factors may cause mechanical obstruction—edema of the glottis, foreign material, and inflammatory reactions in peripharyngeal structures These factors cannot be as easily managed as the tongue More skill and more elaborate equipment will be necessary

A word as to the technic of tracheotomy is not amiss. It is often carried out amidst venous engorgement and the struggles of a half asphyxiated patient. If, as a preliminary step, a bronchoscope can be inserted well into the trachea, respirations will be quieter, venous engorgement will be diminished and the trachea will be located without the slightest delay. All bleeding can be controlled by ligature and a dry wound secured *before the trachea is opened and the tracheotomy tube inserted.*

DR. YANDELL HENDERSON: I wish first to express my appreciation of the opportunity, as a guest of the New York Medical Association, to participate in this discussion.

I wish also to join with Dr. Jackson in the pleasure that it gives us both that the subject of asphyxia and resuscitation from asphyxia has received consideration in this discussion. Dr. Jackson from his side—that of bronchoscopy—and I from mine—that of inhalational treatment—have worked for 25 years to interest the medical profession in this subject. And this discussion this morning shows that at last the profession is interested. Now progress should be rapid.

I missed Dr. Flagg's paper, but I know that he presented his device and technic for the passage of a sound into the trachea for the administration of insufflation of oxygen and carbon dioxide. And I can testify to the practicality and effectiveness of this method of resuscitation. He showed me just once how to use his device, and I was able immediately without the least difficulty to bring

a baby's glottis into view and to pass a sound into it. The operation is extremely simple. Dr. Flagg has rendered a great service in developing his device and technique and in bringing it to general attention.

As regards Dr. Barach's paper, I wish first to testify to the great value of the work he is doing in developing the clinical application of inhalational therapy for pneumonia, and for cardiac diseases, *in which there is a condition of chronic asphyxia.* I believe that he is probably right that for the cardiac cases the addition of carbon dioxide to the oxygen is not called for. But for pneumonia I believe a certain amount of carbon dioxide is beneficial; how much, is still uncertain. We hope that Dr. Barach's experience will contribute largely to deciding this question.

On the question of how strong the oxygen should be, my opinion is that it should be strong enough to overcome cyanosis. No one should ever be allowed for any time at all to be at all cyanotic.

I listened to Dr. Jackson's paper with the pleasure that comes from hearing a master of his subject. He is leading to the wider use of the technic that he has developed. And I rejoice to be associated with him in the general movement for the saving of lives from asphyxia. He has said truly that the death rattle is an indication of obstruction of the glottis and asphyxia. I can support and expand that statement, for in nearly all possible ways of dying the terminal state, when respiration and the circulation are failing, is one of asphyxia.

GUARDING HEALTH IN SUMMER CAMPS

Health conditions in summer camps in the State are being carefully watched by the State Department of Health, and we are informed that an advisory committee has been appointed by the Department as an initial step toward securing better compliance with the provisions of the State Sanitary Code relating to summer camps for children and camp sanitation.

Approximately one-quarter of such camps are operating each year without the permit of local health authorities required by the Code, the Committee estimates. About 200,000 children are scheduled to attend camps in New York this summer. The protection of these children now represents a major health problem. The Committee decided to appoint a subcommittee to consider the drafting of legislation providing for the licensing of summer camps by the State Commissioner of Health, with the payment of a fee, and for the establishment of suitable machinery in the State Department of Health to maintain adequate sanitary supervision and advisory service to camp directors.

The operation of a summer camp without the required permit of the local health officer is a misdemeanor, but the Committee believes a large number of camp directors are inadvertently violating the Sanitary Code due to ignorance of its requirements. It was reported to the Committee that in some instances, although application has been made for camp permits, local health officers have failed to make the required inspections and issue the permits.

A large majority of directors of organized summer camps for children realize their responsibility for the health and safety of the children under their care and would welcome more effective health regulation and supervision, the Committee believes. It was agreed that the State Department of Health immediately circularize the directors of camps of which it has record, calling attention to the sanitary code requirements and stressing the importance of safe water and milk supplies, and that a communication be sent to health officers in the areas in which camps are likely to be located, urging prompt but careful inspections and investigations before the issuance of permits. The Committee indicated that it favored the use of pasteurized milk in summer camps whenever available.

NEW RULING ON THE KISS PERIL

An epochal decision on a vexed question, or moot point, or whatever it may be, was made at the annual meeting of the California State Dental Association. It can be construed, if desired, as a repeal of the prohibition of osculation. "There are germs in every mouth," said Doctor Thomas B. Hartzell, chairman of the American Dental Association's research committee and former president of the association. "But," he added "you'll find the same germs in all mouths—the girls' as well as the boys'."

CLINICAL EXPERIENCE WITH VITAMIN D MILKS

J M ILWIS MD

New York City

In a recent investigation concerning the incidence of rickets among infants enrolled in various health stations in New York City, it was found that 50 to 60 per cent of them showed clinical evidence of this disorder during the winter months. Severe rickets were noted in 10 per cent of the white and 20 per cent of the colored infants. It is evident therefore, that the eradication of rickets is still a major health problem. This situation is all the more surprising when we consider that there are on the market a number of preparations which have specific antirachitic properties, as for examples, cod liver oil, viosterol, halbut liver oil, concentrated cod liver oil, etc. The disadvantages associated with the use of these antirachitic agents is that of necessity they require for their administration the cooperation of mothers. On questioning 100 mothers, in the health stations three years ago, regarding the use of antirachitic preparations, it was found that, although most of them were advised to use either cod liver oil or viosterol, a large proportion did not heed this advice. Some complained of the disagreeable odor of cod liver oil, some stated that the infants either refused or regurgitated the oil, while others objected to the expense of these preparations. In private practice the number of infants receiving antirachitic therapy is, of course, much higher, but from a communal point of view, a considerable number of infants are not receiving the benefit of vitamin D during the winter months.

Since milk is the universal food for infants, it is only logical that attempts should have been made to incorporate vitamin D into this basic food. The administration of vitamin D, through the medium of milk, would be automatic and would therefore not require the cooperation of mothers. The following methods have been employed to fortify milk with vitamin D: (1) irradiating milk by means of the carbon arc lamp, (2) feeding cows irradiated yeast or ergosterol, and (3) adding a vitamin D containing preparation to milk.

IRRADIATED MILK

In 1925, Hess¹ reported that milk could be endowed with antirachitic properties as a result of exposure to ultra-violet radiations. Since then, irradiated milk has been used for the prevention and cure of rickets in many countries. Cowell,² of England, Scheer,³ of Germany, Wieland,⁴ of Switzerland, as well as Kramer,⁵ of this country, have reported favorable results with the use of this milk. In the winter of 1931-1932, Hess and Lewis⁶ carried out an extensive investigation concerning the prophylactic and curative value of milk which has been irradiated by means of the carbon arc lamp. This study comprised 102 infants, and the results may be summarized by the statement that none of the 88 infants receiving this milk for preventive purposes developed rickets as evidenced by roentgen examination and 14 infants who showed evidence of this disorder at the beginning of the study, manifested marked healing in the roentgenograms after having received 24 oz of irradiated milk for one month.

Biological assay of irradiated milk employed in the afore mentioned study revealed about 55 Steenbock units in one liter of milk. Repeated tests showed that the potency of the milk did not vary to any great extent. In view of the fact that most of the infants received 24 oz of milk, only 42 rat units were required to prevent or cure "roentgenologic" rickets as compared with 600 units which are necessary to accomplish the same result when viosterol is given, and approximately 160 units when cod liver oil is given. The ratio of effectiveness of irradiated milk to cod liver oil and viosterol in the infant from the standpoint of rat units is therefore about 15:4:1. A probable explanation for the discrepancy in behavior of antirachitics in the infant as compared with the rat will be given later on in the paper.

In regard to the minimum amount of irradiated milk which is sufficient to protect infants against rickets, our experiences of last year might be cited.

Sixteen ounces of irradiated milk were given to 6 rachitic infants, and after one month definite healing was noted in 5 instances. The infant which failed to respond favorably was colored and was suffering from a very advanced type of rickets. During the past winter 2 colored rachitic infants were given 12 oz. of irradiated milk daily in order to determine the antirachitic effect of this small amount of irradiated milk. In one infant healing was brought about after one month, whereas in the other infant no healing was observed during the same period of observation. The author is, therefore, of the opinion, that in most instances 16 oz. of irradiated milk would suffice to protect infants against rickets. The average artificially fed baby receives approximately 16 to 18 oz. of milk at three to four weeks of age, 20 to 22 oz. of milk at two months, and about 24 oz. at three months of age. Since rickets are rarely manifested in full-term infants under two months of age, even though they receive no antirachitic therapy, it is evident that infants who are given irradiated milk from the time they are born would adequately be protected against this nutritional disorder.

The irradiated milk which we used for our investigations had been exposed to the carbon arc lamp for a period of sixteen seconds. Recently it has been shown by Supplee that an exposure of sixteen seconds is unnecessarily long, inasmuch as the same degree of activation of milk can be brought about by an exposure of only two seconds. By means of the Rentschler meter it is now possible, according to Supplee, to have recorded in a simple manner the intensity of the ultra-violet radiations emitted from the carbon arc lamp. Consultation with these records will, he hopes, enable the health officer to determine whether the carbon arc lamp has been functioning properly.

In regard to the question of the possibility of toxic effects resulting from irradiated milk, it should be stated that no one has ever observed any untoward symptoms or hypercalcemia resulting from its administration. It seems that the low titre of rat units in irradiated milk would preclude such a possibility. Furthermore, feeding rats 10,000 times a therapeutic dose of irradiated milk for a period of months did not bring about any deleterious effects, or any abnormal histological changes in the tissue.

VITAMIN D MILK OBTAINED FROM COWS FED IRRADIATED YEAST OR IRRADIATED ERGOSTEROL

Three years ago, Thomas and Macleod⁷ reported that the antirachitic potency of milk can be augmented by feeding cows irradiated yeast or irradiated ergosterol, and at about the same time Hess⁸ and his coworkers described their clinical experiences with milk produced in this manner. Their study was carried out in two infant welfare stations in New York City, and the procedure was similar to that employed in the investigation of the clinical value of irradiated pasteurized milk. One hundred infants were divided into four groups: The first group received milk from cows fed 30,000 units of irradiated yeast, the second, milk from cows fed 60,000 units of irradiated yeast, the third, milk from cows fed 100,000 units of ergosterol, and the fourth, milk from cows fed 200,000 units of irradiated ergosterol. Biological assays of these milks revealed the presence of 80 rat units in a liter of milk which was obtained from the cows fed the lesser quantities of irradiated yeast and ergosterol, and 160 rat units in a liter of milk, which was obtained from cows fed the larger quantities of these antirachitic substances. It will be noted, therefore, that three times as many units in the form of irradiated ergosterol, as irradiated yeast were necessary to produce milk of similar biological titres.

The clinical results of this investigation showed that 24 ounces of milk containing 160 rat units of vitamin D per liter prevented or cured "roentgenologic rickets" whereas a similar amount of milk containing 80 units per liter failed in some instances to prevent or cure this nutritional disorder. In a survey last year, concerning the appraisal of various antirachitic agents from the standpoint of rat units, Hess and Lewis⁹ deduced that 24 oz. of "yeast" milk containing 100 units per liter should protect against or cure "roentgenologic rickets" which is an expression of the moderate and severe forms of rickets. Mild cases of clinical rickets as evidenced by beading of the ribs and craniotabes, developed in a number of instances, but they emphasized the fact that in their experience, no antirachitic agent can be relied upon to prevent the development of mild clinical rickets. As far as we know, there are no deleterious effects resulting from mild rickets, and

the goal of those interested in the eradication of this disorder, should be concerned with the prevention of the moderate and severe types since the latter are frequently responsible for contracted pelvis and marked deformities of the chest.

For the past two or three years, milk from cows fed 60,000 units of irradiated yeast has been used commercially in New York, Boston, and Philadelphia, as well as in other large cities. As stated previously, there are at present 160 rat units in the liter of milk produced in this manner, although 100 units per liter would be sufficient. It would seem that the production of so-called "yeast milk" should be limited to the larger certified dairies which can be relied upon to supply the requisite amounts of irradiated yeast to the rations of the cows. Assays of the milk should be made from time to time by reliable laboratories and should be checked by local health authorities.

COD LIVER OIL VITAMIN D CONCENTRATE ADDED TO MILK

Clinical investigation of the antirachitic value of milk to which a cod liver oil vitamin D concentrate was added has been carried out by Barnes, of Detroit, and the results have been reported briefly by Zucker¹⁰. Fifteen rachitic infants were given milk containing from 100 to 150 units of cod liver oil concentrate. Favorable results were noted as judged by a return toward normal of the calcium and phosphorus content of the blood and cases of complete healing as judged by x-ray were recorded in about forty days.

CRYSTALLINE VITAMIN D INCORPORATED IN MILK

During the past winter the author in collaboration with the late Dr Alfred F. Hess investigated the antirachitic value of milk containing crystalline vitamin D. This substance has been isolated from irradiated ergosterol by Windaus in crystalline form and has marked antirachitic properties. For example, one milligram is equivalent in potency to approximately 13,000 Steenbock rat units.

A group of 8 infants was given 24 oz of milk containing 42 units of crystalline vitamin D, another group of 9 infants was given 24 oz of milk containing 80 units of crystalline vitamin D. A third group comprising 9 infants was given 80 units of crystalline vitamin D in corn oil, in order

to determine whether vitamin D administered in milk is more effective than when administered in oil. No attempt is made to give the details of this investigation which will be reported at a future date, but the results are summarized by stating that in every instance in which 80 units of crystalline vitamin D were given in the medium of milk definite healing was noted on the roentgenograms after four weeks, whereas only 3 of the 9 rachitic infants receiving 80 units of crystalline vitamin D in oil showed healing during the same period of observation. Of the 8 infants receiving 42 units of crystalline vitamin D in milk, healing was observed one month later in 6 instances. The results of this investigation indicate that the medium of milk allows for better absorption or utilization of vitamin D than does corn oil and offers an explanation why vitamin D milks as a group require fewer units than viosterol or cod liver oil to prevent or cure infantile rickets.

It is evident that vitamin D milks irrespective of the manner in which they are produced are capable, not only of preventing but also of curing rickets. If all artificially fed infants were given vitamin D milk, rickets would indeed become a rare disorder. It should be mentioned, however, that occasionally infants will develop rickets in spite of receiving a liberal supply of vitamin D. These cases may be resistant to treatment, even with excessively large amounts of vitamin D, and should they be encountered in infants receiving vitamin D milk, it should not be deduced from such an experience that the milk has been a failure.

In order to determine the effect of the administration of irradiated milk to lactating mothers on the course of rickets in breast fed infants 3 nursing mothers whose babies were suffering from rickets were given one quart of irradiated milk. At the end of one month, roentgenograms were taken of the wrists and in no instance was healing noted. From this experience involving only 3 cases it is obvious that the administration of irradiated milk to lactating mothers cannot be relied upon to augment appreciably the vitamin D content of their breast milk. In a recent report Bunker, Harris, and Eustice¹¹ showed that 24 oz of yeast milk given daily for a period of two weeks to nursing mothers brought about an increase of the vitamin D content of breast milk so that one quart con-

tained approximately 8 rat units, a potency inadequate to prevent or cure rickets in nursing infants. Antirachitic agents will have to be given directly to nursing infants in order to protect them against rickets.

Clinical investigations concerning the value of vitamin D milks have been limited almost entirely to rickets. In some reports, however, mention has been made of the effectiveness of these milks in the prevention and treatment of infantile tetany, which is almost always a complication of rickets.

Vitamin D milks should prove of great value in the prevention of osteomalacia (adult rickets), a disorder endemic in some parts of China and India. According to Macy,¹² the addition of vitamin D to the diet of lactating and pregnant mothers brings about an improvement in the calcium and phosphorus retention so that vitamin D milk might be prescribed with advantage to pregnant and lactating mothers. Mellanby and Hess among others, are of the opinion that the lack of vitamin D is an important factor in the development of dental caries. Vitamin D milk might, therefore, have some application in the prevention of this disorder, although as yet no clinical studies have been reported of its use in this connection.

Vitamin D milk might be given with advantage from infancy to adolescence in order to bring about an optimal phosphorus and calcium retention during the growing period. Whether it should be given to adults is a moot question.

SUMMARY

A discussion of the antirachitic value of

various types of vitamin D milk has been given.

Vitamin D milks are very effective antirachitic agents and require fewer units to prevent or cure rickets than are necessary in the form of cod liver oil or viosterol.

Eighty units of crystalline vitamin D incorporated in milk brought about definite healing in all of 9 rachitic infants in one month, whereas 80 units dissolved in oil brought about healing in only 3 of 9 rachitic infants during the same period of observation. These results indicate that the medium of milk allows for better absorption or utilization of the antirachitic vitamin and offer an explanation why vitamin D milks as a group require fewer units than cod liver oil or viosterol to prevent or cure infantile rickets.

The administration of vitamin D milks to lactating mothers cannot be relied upon to prevent rickets in breast-fed infants. Antirachitic agents will have to be given directly to nursing infants in order to protect them against this nutritional disorder.

639 WEST END AVE.

THIS AND THAT

A special room has been provided in a school at Monrovia, California, for pupils who need special health training. There they will have in addition to their regular school program orange juice, sunbaths when the weather permits, a hot lunch prepared by an expert dietitian and a rest period for an hour during the afternoon.

Each child's individual needs will be studied and the school will work closely with the child's home to bring all these substandard children up to normal health.

A drug traffic in Europe has been largely brought under control and the illegal manufacture of drugs has been almost destroyed, according to a report of the Director of the Control Narcotics Intelligence Bureau. But it seems that a fresh danger has arisen in the Far East, where in Manchuria a new field of drug traffic is being opened up, which may in time become

a menace to the world. What appears to be a government opium monopoly is functioning in Manchuria, and this encourages the growth of the local product and the import of Persian opium. Bulgaria is now almost the only European country manufacturing morphine and cocaine, deliberately designed for illicit traffic. The survival of the manufacture in spite of the ostensible willingness of the Bulgarian government to suppress it seems to be due to the occult influence of various Macedonian organizations.

New Jersey doctors have obtained state legislation providing that charges for medical services shall be a lien on awards for injury or illness.

An Oklahoma publication says that the American physician is "the pier of any in the world." Is that why he is called "doc?"

THE WORK OF THE COUNCIL ON PHYSICAL THERAPY OF THE AMERICAN MEDICAL ASSOCIATION

JOHN S. COULTLER, M.D. AND HOWARD A. CARTER, B.S. in M.L.

Chicago, Ill.

Fifty years ago, Weir Mitchell brought to the attention of the medical profession the importance of physical therapy. The indifference with which the profession received his message and its disregard of the field of physical therapy has been largely responsible for the growth of a series of cults whose practices center around fragments of this form of therapy. Due to the successful use of physical therapy in caring for injuries in the World War, there was a large production of complicated machines and apparatus utilizing simple physical agents in the treatment of many diseases and disabilities. The manufacturers spent large sums of money advertising these machines and none advertised the simple, cheap, and easily obtainable physical agents, of heat, massage, water, and exercise. In the minds of most physicians, therefore, the term physical therapy soon evoked a picture of an office filled with complicated electrical apparatus and an assortment of lamps. The medical profession as a whole had no courses in physical therapy in its medical curricula. Most physicians had no access to authentic information of the value of these machines and were obliged to receive their knowledge through inspired literature in second rate medical journals, by courses given by manufacturers of instruments, and through demonstrations by salesmen. This sale of machines was not limited to the medical profession, but machines were often sold to beauty parlors, clubs, and to various cults. Not satisfied with this success, manufacturers advertised and sold their machines directly to the public. Undoubtedly, every member of the medical profession is familiar with the false, exaggerated, and unwarranted therapeutic claims made for the use of ultra-violet lamps sold to the public.

Observing this deplorable condition, Dr. Joseph F. Smith, of Wisconsin, in 1925 submitted a resolution to the House of Delegates of the American Medical Association setting forth the apparent need for the creation of some official body that might attempt to bring about a rationalization of

physical therapy. The resolution was adopted, and the Council on Physical Therapy was organized in September, 1925.

The aims of the Council are (1) to protect the profession and the public from misleading and deceptive advertising in connection with the manufacture and sale of physical therapy devices, (2) to disseminate such reliable information as the Council may possess or acquire in the use of physical therapy, (3) to stimulate instruction designed to aid the practicing physician in the choice and application of sound methods of physical therapy, (4) to act in an advisory capacity to the profession and the public in matters pertaining to this particular field of therapy.

How are these aims accomplished? To protect the profession and the public from misleading and deceptive advertising in connection with the manufacture and sale of physical therapy devices it has been necessary to devote much of the time of the Council to the consideration of physical therapy apparatus, including that which has been submitted by manufacturers with a view of securing the Council's acceptance, and that which is offered for sale without submission. The list of accepted and rejected apparatus is proof of the earnest effort that has been made to properly evaluate the evidence that has been submitted to the Council, to safeguard the interests of reputable manufacturers and to protect the medical profession and the public.

In ultra violet radiation therapy some of the important results of the Council's investigations have been incorporated into its revised "Regulations to Govern Advertising of Ultra-violet Generators to the Profession." The cooperation of the Council on Dental Therapeutics of the American Dental Association was secured to determine the value of ultra-violet radiation in dentistry. The Council has cooperated with the International Congress on Light by sending a representative to its last meeting, and by adopting its suggested standard unit of dosage for ultra-violet

radiation, that is, 20 microwatts per square centimeter of homogeneous radiation of wavelength 2967A as the erythral unit (E.U.).

The investigation of high frequency electrical machines has required much time and effort of the Council. The Council cannot afford to accept an electrical apparatus until it has been thoroughly tested as to its insulation, safety, and efficiency. A saner interpretation of the value of high frequency electrical currents to the general practitioner was made by the publication of Council-adopted articles on "Medical Diathermy," "A Preliminary Statement to Acceptance of Diathermy Apparatus," and "The Examination of Diathermy Machines for Local Diathermy Treatments and Requirements for Acceptance of These Machines by the Council on Physical Therapy of the American Medical Association."

The Council has published a critical article on Oxygen Therapy and has investigated resuscitation equipment and oxygen tents.

The Council has on file lists of accepted apparatus. It can now be stated that the medical profession and hospitals should buy only high frequency electrical machines and ultra-violet lamps that have been accepted by the Council, as these are the only machines that have been thoroughly examined for safety and efficiency by a disinterested group. There are a large number of devices that might be regarded as coming within the purview of the Council. However, to facilitate the work of the Council, two lists of devices have been formulated: one a list of apparatus that the Council will consider and report on as soon as possible, and the other a list of articles that cannot be given immediate consideration.

The second aim of the Council is to disseminate such reliable information as it may possess or acquire on the use of physical therapy. The most important step in this aim was the publication of the Handbook of Physical Therapy, in which many valuable and authoritative articles previously published in the *Journal of the American Medical Association* were brought together. The third printing of the first edition of this book is nearly exhausted and the second edition will be ready for publication by the end of this year.

At various intervals the Council con-

tinues to publish in the *Journal* articles on the use of physical therapy. To aid the medical profession in the accumulation of acceptable evidence on the value of physical agents in the treatment of disease or injuries the Council adopted and published the article "Evaluation of Methods Used in Physical Therapy." This article deals with the kind of evidence that is acceptable to the Council relative to its consideration of apparatus and for the evaluation of treatment methods used in physical therapy.

To stimulate research, each year the Council awards small grants to critical investigators for purchasing needed materials for their work. The results obtained with these grants have been encouraging.

The third aim of the Council is to stimulate instruction designed to aid the practicing physician in the choice and application of sound methods in physical therapy. This must start in premedical education. Early the Council realized this and published an article on this subject in 1926.

The Council has published articles on "Medical Education" in 1930 and 1931 and will soon publish another on "The Teaching of Physical Therapy to Undergraduate Medical Students."

While the education of the medical student is important, it is clear that there remains a field within the medical profession that is not reached by the schools. This field is the extension to practitioners at large information more or less practical on the use of physical therapy. A few institutions give postgraduate work in physical therapy, but the total number of physicians who can afford the time for such an enterprise is relatively limited. There is no question of the desirability of extending to the profession as a whole, especially in those regions not in touch with the teaching centers of medicine, a working knowledge of the general principles underlying physical therapy. In order to do this, the Council is planning to follow the pioneer work of your State Society in creating a physical therapy committee. Recognizing the value of Dr. Richard Kovacs' work in this plan, the Council recently adopted and published an article by him on "Physical Therapy Committees in State and County Medical Societies." It is the hope of the Council that these committees will hold seminars for the postgraduate instruction in physical therapy for the practicing physician.

Another method of promoting sound education in physical therapy is the exhibition and demonstration of physical therapy at the annual session of the American Medical Association. These exhibits have been loaned to several state and other scientific medical societies.

In the education of physical and occupational therapy technicians, our Council has secured the cooperation of the Council on Medical Education in the formulation of the essentials for schools for these technicians. By next year this Council will probably publish lists of approved schools for physical and occupational therapy technicians.

The final aim of the Council is to act

in an advisory capacity to the profession and the public in matters pertaining to physical therapy. This is done largely through correspondence and the success of this effort is demonstrated by the gradual increase of correspondence of the Council.

The Council has been in existence over eight years. It is believed that the Council has played an important part in the progress that physical therapy has made during this period. It was created by the medical profession for the medical profession and needs your cooperation. Only with your cooperation and understanding of the problems of the Council will it be able to help physical therapy to reach the position in the art of healing which it deserves.

ONE DOCTOR'S PLAN—IT WORKED, TOO

Any plan for collecting fees that works is well worth noting just now. In this case the collecting is done by an odd looking Indian basket as the story goes in *Medical Economics*. The doctor, it seems, had two offices, one at his home in the industrial part of town where the people were small wage earners and the other downtown patronized by the well to do. With hard times the wage earners failed to pay and the doctor soon found himself in shallow water financially. What to do? His eye fell on the old Indian basket, which he had used for a catch all. He put it in a prominent location on his desk and suggested that each patient drop a dollar bill in it as he left. The first day the patients put in \$9, and not one of them had paid a cent before for months. The doctor adds, "This odd looking basket has never ceased to function since that time. Factory people do a good deal of gossiping. This fact, supplemented by my daily talks with patients, established the dollar payment habit in the beginning and has kept it functioning ever since."

To my patients the plan looked good as it enabled them to maintain their self respect and to keep square. At the same time discharge all my time a patient car money instead of.

We are assured that this doctor has a beautiful home and two modern offices. is a director in a leading bank has educated three daughters and a son in leading American universities and spends a month each year hunting and fishing in the north woods.

On the basis of a successful practice in the factory district of his city his reputation has spread throughout the community in which he lives, so that he now has hundreds of patients who pay him standard fees. Both within and without the profession he is highly respected and he still maintains the institution of the dollar basket for his factory patients.

A NEW ALLY AGAINST MEDICAL PEONAGE

An ally in the fight against compulsory state medicine appears in the *Christian Science* camp. This faith may perhaps deny the value of scientific medicine but it recognizes the rights of the individual and sees peril in any system that would force the physicians and the public into a mechanized regimentation of healing. The editor of the *Christian Science Monitor* asks if those who do not feel the need of medicine sufficiently to seek its aid—even when offered free in countless clinics—will "permit themselves to be saddled with medical peonage under a compulsory plan. He makes this engaging summary of the situation. The family physician who brought kindness ready sympathy, and unselfish service in large quantities along with his pills and potions has been passing from the American scene, more and more his place has been taken by a complex mechanism, a highly departmentalized professionalism, with impersonal efficiency of

its dominating sentiment. Now there is a tentative plea for a broad organization of state medicine as recently outlined by the secretary of the Milbank Memorial Fund of New York. This plan utterly impersonal, purposes that the entire American population—including that 62 per cent which the fund's spokesman says receive no medical, dental, or eye care of any kind—shall be coerced into supporting financially and yielding physically to the domination of a group of state employed medical men.

"It is difficult to understand why every citizen—including those who by choice would adhere to a rival school, to no school, or those who depend upon prayer for healing—should be compelled to comply with such a regulation. Incidentally, it is strangely foreign to the legend of the family doctor who worked under the motto 'To each according to his need, from each according to his means.'"

EARLY DIAGNOSIS OF CARCINOMA OF THE CERVIX

NATHAN P. SEARS, M.D.

Syracuse

Since as yet no specific cure for cancer has been discovered the results obtained in treatment of this disease depend for their success upon early diagnosis. There is no organ in the body which is better adapted to the study of cancer than the cervix uteri. It presents symptoms which are externally visible, it is easily accessible for examination and biopsy, and when removed by surgery or treated by radiation leaves no visible scar, no loss of vital function. The grading, according to extent, as presented by the League of Nations Cancer Committee has given common terms by which the results of various clinics can be compared. Although not entirely free from the personal equation it is far more accurate than the classification according to "operable" and "inoperable" which varied according to the boldness and optimism of the attending surgeon. The marked difference in "curability" between Stage I and Stage III or IV cancer is sufficient to stimulate the most pessimistic to increase his vigilance in the battle for early diagnosis. If cancer of the cervix is to be controlled, and this means that diagnosis must be made early, there must be complete cooperation between physician, patient, and pathologist. Each must share in the responsibility, and upon the physician and the pathologist must fall the greatest burden.

The medical profession must be prepared not only to recognize early cancer but also to bear the burden of educating the prospective patient. It should be the duty of every medical school in the country to indelibly imprint upon the mind of each graduate the methods of detecting early cancer, that *early* cancer only can be controlled, and that it is his duty to teach the public the facts about such lesions. It should not be possible, as is frequently the case, for patients to report abnormal bleeding to their physician and then be allowed to go for from six months to a year without a diagnosis. Within the last year the author has had the misfortune to see 3 such cases, each presenting herself with a Stage III or IV cancer of the cervix.

Every woman should be taught by every available means that irregular bleed-

ing or unusual discharge may be a sign of early cancer and that early cancer has a favorable prognosis. Within a month one of the author's patients whose sister has cancer of the cervix quoted her doctor as saying; "No cancer ever gets well. If the patient has a cancer, she dies; if she doesn't die she didn't have cancer." This doctor is an elderly man whose word has great weight in his community. What hope have we of fighting this disease when patients are given such instruction? Each woman should be taught that abnormal bleeding is not a normal accompaniment of the menopause. She should be taught to present herself early to a competent physician and that from him she can expect a thorough examination and careful advice and not the often careless reply that she will be all right as soon as her "change" has passed. She must be taught that if she does not get careful consideration, she must seek advice elsewhere. Of these things the most important is that she must be taught that early uterine cancer has a good prognosis, otherwise she will dread, fear, and postpone the examination that would possibly disclose an early lesion.

Physicians, either specialists or practitioners, must understand that cancer has no definite symptoms. Bleeding and discharge are symptoms presented by cancer as well as many another condition, and it is our duty immediately to determine by careful examination the nature of the lesion. The question is not, what are the possible causes of bleeding, but, is the bleeding due to a benign or malignant lesion? The idea that cancer is always associated with a profuse, foul, watery, blood-tinged discharge should be abandoned. To-day the symptom that most quickly arouses the author's suspicion is a slight spotting of blood, often, but not always, exaggerated by trauma, either intercourse or douching. There may also have been a recent vaginal discharge or a change in character of a preexisting one. Let me emphasize again that, although these symptoms may be due to a benign condition, this cannot be assumed from the history.

Since, therefore, it is evident that early cancer has no distinctive symptoms, its

diagnosis depends upon examination. Palpation is of little value in the early lesion. When one feels a hard fixed cervix, a cauliflower mass, or a crater-like ulcer, this lesion is no longer early cancer. Digital examination in the early lesion frequently shows no more than the blood-stained glove finger. Visual examination through a well-fitted speculum and using a good light should be demanded by every woman who is suspected of having any lesion of the cervix. Examination while bleeding, except during normal menstruation or threatened abortion, is not contraindicated, and this point should be strongly emphasized. It is at the time of the bleeding that one can frequently determine its cause.

Early cancer may appear as a small, elevated nodule only 2 or 3 mm in diameter, as a slight papillary growth, or as a shallow ulcerated area. Each of these lesions has one characteristic, it usually bleeds freely when touched with a smooth object. Early lesions are apt to appear at the junction of the squamous and columnar epithelium at the external os. More advanced lesions appear as larger and more distinct masses showing signs of necrosis. They have an opaque granular appearance and crumble and bleed when pressed against. On the contrary, inflammatory lesions are more resilient, glistening, and although they may bleed, they are quite different in appearance. This difference, however, may be apparent only to the experienced gynecologist.

Recently Schiller has presented a test which bids fair to help not a little in locating suspicious lesions. This test is based upon the brown staining of cell glycogen by iodine and is carried out as follows. Lugol's solution* is poured into the vagina through a speculum and then held against the cervix for two minutes by means of a tampon. After removing the tampon, the normal cervix is seen to be stained a mahogany brown while abnormal lesions such as early cancer, leukoplakia, or erosion show no staining. This may often direct our attention to the suspicious area.

Biopsy is, in early cancer, the final word. There have been some who fear this procedure thinking that dissemination of cancer will follow. However, it seems to most gynecologists that the value of tissue

study far offsets any theoretical danger of spreading the disease. There are, however, a few warnings. Promiscuous biopsy on definitely benign cervixes is unnecessary, biopsy in sloughing advanced cancer is unnecessary, and as these are so frequently infected with virulent streptococci there may be danger of general infection. Biopsy of early lesions can be carried out in the office with a rongeur or with scissors. The edges of the wound should be immediately cauterized with the actual cautery. If a small electrosurgical knife is used care should be taken not to damage the tissue to be examined. Tissue removed should be put in 10 per cent formalin, properly labeled and sent to the laboratory. The sending of the tissue to two or more laboratories should be condemned. This often leads to confusion since one laboratory may receive a piece of malignant tissue and another benign tissue. This practice is also not without danger for if the pathologist in whom the physician has the most confidence receives the benign tissue, the patient may not receive the proper treatment. All laboratories should use all the tissue removed from suspected cancer and make many slides, any of which could be sent for consultation.

Frozen section, except in laboratories where the pathologist is thoroughly familiar with this technic, should not be used for the diagnosis of these early lesions in which detail study of the cell is necessary. Permanent celloidin or paraffin sections can be made in any laboratory in 24 hours if necessary.

Occasionally a patient appears, giving a history of irregular bleeding, and a most careful search fails to reveal any lesion. In such cases we must suspect cancer above the external os. Such a lesion may be located by gently passing a smooth instrument into the cervical canal, this procedure will cause a small stream of blood to appear. This at least tells one where to obtain the material for examination and in this case curettage is most helpful.

Let us not forget that incipient cancer of the cervix may exist together with some more evident lesion. For example, an easily demonstrable fibroid may be accepted as the cause of bleeding when a more critical examination would reveal an early cancer. The author believes that every woman presenting any bleeding suspicious of cancer should have a careful study for malignancy no matter what other condition

* Lugol's Iod gm 1, Pot Iod gm 2 distilled water 300 cc

is present. If this were done more often, there would be fewer instances of cervical cancer discovered after supravaginal hysterectomy.

Although no cause of cancer is known, there is considerable indication that chronic inflammation is at least an important factor in the development of cervical carcinoma. The high percentage of cases developing in lacerated and infected lesions of the cervix has been common knowledge for many years. Many pathologists have called attention to the apparent similarity between the reaction of healing and of early cancer. Overholser and Allen have been able to produce in the cervix of the monkey, by the administration of ovarian hormone together with traumatization of the cervix, lesions indistinguishable histologically from cancer. Because of the possible relationship between chronic irritation of the cervix and malignancy, all chronic lesions should be eliminated, usually by means of the cautery, in the hope of preventing the development of carcinoma.

In the healing of cervical erosions, ectropion, and similar conditions, squamous epithelium may grow along the healing surface to be covered by the columnar epithelium and glands, giving the appearance of invasion. At times, probably due to metaplasia, the columnar epithelium lining the glands may be replaced by squamous epithelium giving the appearance of deep strands of invading cells.

Schiller, in a recent article speaking of the appearance of the border of advancing carcinoma, makes the following statement: "If the carcinomatous area bordering the carcinoma is recognized as carcinoma, and we are logically bound to accept this assumption as true, then from our study of the uninterrupted series the smallest carcinomatous layers with no down growth

must be considered as carcinoma as well." If we can accept Schiller's statement, and I, personally, believe we can, it becomes the duty of the pathologist to differentiate benign and malignant lesions by cell study alone. In other words, is not the cell of a carcinoma which has not yet invaded normal tissue just as malignant as the one already past its normal boundary? Is a rabid dog any the less rabid because he has not yet broken loose from the barrier surrounding him? In nonmalignant lesions, even though there is apparent invasion, the cells maintain their normal morphology and arrangement, while in the malignant state they show loss of polarity, variation in size and staining intensity of the nuclei, and numerous mitotic figures. In some instances, however, the line between malignant and benign reaction is so obscure that an unqualified opinion cannot be given. In such cases experience and sound judgment must direct the course to be followed.

In conclusion, it should be stated that it is the duty of every member of the medical profession to keep constantly in mind the following: First, early cancer has an excellent chance of being completely arrested in its growth and late cancer is hopeless. Second, early cancer can only be diagnosed by careful cooperation between patient, physician, and pathologist. Third, we must teach the women that early cancer is controllable so that they will not dread and postpone examination. Fourth, when they appear, they are entitled to a complete and careful examination. Fifth, all chronic lesions of the cervix should be intelligently treated in the hope of preventing cancer. Sixth, biopsy is simply and harmless if properly done and should be carried out whenever an area suspicious of cancer is found on or in the cervix.

BABIES AND OTHER THINGS

In 1900, 170 out of each 1000 babies born alive died during the first year. In 1932 the figure had fallen to 58. In other words, out of every 1000 babies born in 1932, 112 were spared the case, they would have suffered in 1900. A bleeding to 1920 stood about 7 chances out of allowed to go a prey to diphtheria. The risk year without a in 1930 was about one-third as year the author

see 3 such cases, strong fondness for babies. The with a Stage III or strong. The doll is their Every woman live baby in the house is a Every woman Sic doctor in Pennsylvania every available means 5, had hitherto been an

obedient child. One night, however, she absolutely refused to say her prayers. Mother reasoned with her and then came the explanation: "I have been saying my prayers every night for six months praying for a baby sister, and none came; Madeline across the way does not say her prayers at all and last night her mother had twins."

The case against socialized medicine was put in a neat nutshell by Dr. W. A. Mulherin, Professor of Pediatrics at the University of Georgia, in an address before the Tennessee Medical Association. "When politics enters the profession," he said, "efficiency goes out the window."

THE MODERN PSYCHIATRIC HOSPITAL IN RELATION TO PUBLIC HEALTH

W W WRIGHT, M D

Marcy

In spite of all that has been written in recent years in regard to mental disorders and in spite of all the lectures that have been given and all the public clinics that have been held, the general public has still but a vague and a distorted notion of the problem.

A few centuries ago the field of grave mental disorder belonged to the field of demonology. The insane, it was believed, were possessed of devils which had to be expelled from the body of their possessor by castigation and exorcism. Many of these demons were known and were called by name as they left the body of the host. Devils were the producers of evil and sin, and the possessors thereof, being sinful or accursed, were made outcasts.

The belief that the mentally ill are possessed of devils has faded but the curse remains. Even to day mental disease is often regarded by the family as something to be ashamed of, a topic to be avoided or spoken of in whispers. As a result of this feeling about mental disorders a state hospital is regarded as a place to be ashamed of. It is often indicated by the pointing of the thumb, its name is not spoken but it is designated by the term "over there."

The main concept of a state hospital is, that it is a form of prison, for the first things that the casual visitor asks to see are the padded cell and the dungeon. Such queries though come not alone from the laity but from the medical profession as well. It was with the idea of helping to correct some of these misconceptions and some of the misconceptions in regard to the causes of mental disorders that the present topic was chosen.

Probably one of the greatest handicaps to the general practitioner in his effort to treat mental disease is his belief that it is hereditary. Such a concept naturally leads to a feeling of hopelessness and a desire to be rid of the patient.

As proof of the correctness of the theory of heredity the Mendelian law is quoted. Mental disease, it is said, is a unit character.

In presenting this argument the fact is overlooked that there are forty six groups

and subgroups under which mental disorders are classified and that each of these groups has in most instances, an etiology different from the others. Also, the fact is overlooked that there are all gradations of mental aberration from a frank psychosis, on the one hand, to a slight deviation from the normal, on the other.

On first thought, one has a feeling of discouragement at the lack of apparent accomplishment in the prevention of mental disorders. On second thought, one is impressed by the vastness of the field and the necessity for prolonged and persistent effort in order that satisfactory results may be obtained.

In regard to the plans for disseminating knowledge of the problems of mental disorders much has already been written. Various methods of approach to the subject have been stressed, namely, adequate teaching of the subject in the medical schools, the importance of giving special courses to public health nurses, of extending clinic facilities for both adults and children, the need of psychiatric examinations and treatment of problem children in the schools, and the importance of visits to the state hospitals by service clubs, legislators and other public officials. But more work yet remains to be done.

Much may be accomplished if all state hospitals will give at regular intervals clinics and demonstrations to health officers at conferences arranged for their benefit. Such conferences eventually should be extended to include the general practitioners. Both groups, it is felt, will naturally welcome such conferences when they discover that a knowledge of mental disorders will benefit them in their work. In addition they should be encouraged to consult the hospital physicians, either at the hospitals or at the clinics, about the mental abnormalities of their patients.

The plans thus far outlined deal largely with extramural activities. The intramural activities of a psychiatric hospital as related to the treatment and rehabilitation of patients remains yet to be considered.

The term psychiatric hospital is used for the purposes of including the licensed

private institutions for the care and treatment of mental disorders. Many of these institutions, in addition to the excellent hospital facilities which they offer, render meritorious public service through the medium of their well-trained medical officers. But since the problem of caring for the mentally ill belongs primarily to the state, the rôle of the state hospital as a psychiatric hospital will be given most consideration.

To a group of well-trained psychiatrists it seems almost trite to enumerate the causes and the conditions which lead to mental illness.

Of the fact that the problems of life are year by year becoming more complicated and that, as a result, greater and greater demands are made on the individual to solve these problems, everyone is well aware. Every physician, also, is conversant with the fact that many of these problems the individual is unable to solve alone. Whether the problem can, with the physician's aid, be solved at the home or the clinic or whether prolonged hospitalization will be necessary, is a fine distinction which private physicians are often required to make. If the patient is admitted to a state hospital, then the responsibility for his care is transferred to the state.

On admission the idea of the patient, and often that of his relatives, is that he is in custody, virtually a prisoner. To correct this idea, therefore, is of utmost importance but to do this, a hospital atmosphere must be created and maintained in every department of the institution and among all the employees. However, such an atmosphere should be real and not artificial. Hence, when the patient is admitted, he should be regarded as a medical problem and every effort should be made to discover the presence or the absence of physical illness or glandular dysfunction so that when the examinations are completed appropriate treatment may be instituted.

To make such examinations and to give such treatments as are required, the standard equipment used by general hospitals for the diagnosis and the treatment of both medical and surgical conditions is necessary. To aid in carrying out these procedures the services of the visiting and the consulting staff of the hospital are needed, and practically all of the New York State hospitals, the author is pleased to say, have the advantage of the service of the various specialists in their respective localities. It

is also necessary to have a laboratory which is under the direction of a competent pathologist and which is thoroughly equipped to do clinical and pathological work.

When the bodily organs and the bodily fluids have been examined, it is often recorded that no definite physical ailment has been found, so it is evidence that forms of examination and of treatment not common to general hospital practice are required. To complete the examination, therefore, the mental life of the patient must be investigated. His assets, his liabilities and his experiences, together with his physical state, must be considered and evaluated in the light of his mental state. When the analysis of his condition has been completed and certain forms of psychotherapy have been prescribed, it is often found that in addition special forms of treatment are indicated, such as hydrotherapy, physical therapy, occupational therapy, physical training, and special muscle training.

During the course of treatment it is often necessary to transfer the patient from one service to another, hence it is important that all the data relating to the diagnosis and the treatment of the patient accompany him.

By the time the patient reaches the hospital he is often dissociated and self-centered. He lives in a world of his own creation and has little interest in his associates, hence means must be found to arouse his interest. This is accomplished largely through occupational therapy and physical training. By means of drills, games, and coordinated exercises the individual becomes less self-centered and more interested in his environment. His activities become constructive and purposeful and he develops the spirit of competition. Music also is effective in some instances.

Occupational therapy and physical training are applied usually to selected groups and in designated centers. These forms of treatment are excellent, but often as thus applied they reach only a limited number of patients. It is important, therefore, that these activities be extended so that all the patients in the hospital for whom these forms of treatment are prescribed may be benefited thereby.

To accomplish these purposes it is necessary to have the physical instructors visit the wards at frequent intervals and teach simple drills and exercises to those patients

that are not otherwise provided for. It is also necessary that the ward employees be given the same form of instruction that the patients have received so that they may be able to continue the work on the ward regularly each day.

The results of these forms of rehabilitation are usually slow of accomplishment and require painstaking effort over a considerable period of time, but as one reviews the progress that has been made the conclusion is that they are worth while procedures. Occupational therapy, physical therapy, and similar forms of therapy already mentioned are, however, not alone sufficient. They must be accompanied by psychotherapy. As soon as the patient can be induced to discuss his problems then every effort should be made to help him solve these problems. Naturally the earlier and the more thoroughly these therapeutic measures are applied, the better the results will be.

The importance of the social service department in spanning the gap between the hospital and the community is too well and too favorably known to need much comment. One of its functions is to bring many of the facilities of the hospital to the home and to the community in general. Through its efforts contacts are made with other social agencies which would not be possible otherwise. By means of it there is an interchange of ideas between the community and the hospital which are mutually beneficial.

In brief, then, it may be said that each state or psychiatric hospital should be the center for psychiatric advice, teaching, and treatment in its particular district.

DR. H. H. STECKEL: For more than ten years I have been particularly interested in the extramural educational program of several of our state hospitals and although I realize that much work has been done along these lines as has been suggested by Dr. Wright, yet there is still room for improving this very necessary educational program. It is my belief that we shall notice during the course of the next decade a very decided change in the attitude of medical schools with relation to their educational program along psychiatric lines. Two years ago the National Committee on Mental Hygiene sponsored a survey of psychiatric education in medical schools of this country and as a result of their report as well as suggestions made by them, it would seem to me we shall soon see a different attitude on the part of the medical profession toward mental disorder as the younger, newly-graduated physicians filter into the field.

I think there has been for several years a tendency toward a changing attitude with refer-

ence to medical education generally with special emphasis being placed upon the psycho-biological factors therein. New laboratory procedures, mechanical devices designed to improve diagnostic technic, such as the x-ray, cardiograph, et cetera, have tended, it seems to me, to mechanize medical procedure. It is coming to be more and more recognized that man consists not only of a group of organs which are quite highly synchronized, but that he has as well an emotional being which reacts to environmental settings in various ways—very often producing a disturbance of function in the organs already mentioned and thereby not infrequently leading in the long run to definite organic diseases.

During the past few years in the Syracuse Medical College an experiment has been carried on by means of seminars with senior students to emphasize to the student the need for a recognition of social and environmental factors,—not only in the production of diseased conditions but also to the need for the understanding of these environmental factors in rehabilitating the patient. This of course is nothing more than a psychiatric viewpoint or perhaps we might better say a psychobiological viewpoint which is being instilled into the young doctor's mind with no emphasis upon psychiatry, perhaps because of the natural resistance which has for a long time been evident against this specialty. We feel as a result of this experiment better physicians will be the order of the day and more hopeful results will be obtained not only in the field of preventive medicine but in the field of rehabilitation of patients after acute illnesses have subsided.

One cannot fully understand why there should have been for so many years an indifference on the part of the medical school toward this problem of mental disorder when we stop to consider the fact that there are in this country as many beds for mental disorders as there are in hospitals for all other diseases. On the whole, it seems to me, the attitude of the medical profession itself might very appreciably be improved. I presume the average medical man is so steeped in his interest in finding evidence of organic changes to explain symptoms on the part of his patients that he fails utterly to give weight to the emotional elements at play which, if we think in terms of integrated individual, psychobiological approach to understanding of human behavior, undoubtedly play, an important part in the production of very definite organic disease and certainly most frequently in the production of so-called functional disorders.

I wish Dr. Wright had emphasized more forcibly our recent attitude regarding the relationship of heredity and mental disorder. Unfortunately, much damage has been done by the popularization of such studies as the Juke and Kallikak families which by the way, I believe, have been quite definitely discredited by most scientific observers. Not enough emphasis has been placed upon more recent studies along these lines made by observers such as Dr. Canavan of Boston and others in which a more scientific approach to the study was made in using a normal control group. Those of you who are familiar with Dr. Canavan's findings will recall that she found almost as many psychotic individuals in the progeny of a normal group as he did in the abnormal group and many more feeble. I think it is recognized by all that

ground upon which certain types of functional mental disorder arise may be transmitted just as is the physical status, et cetera, but that one must place greater weight upon environmental factors and the experience of the individual as it is concerned in the development of personality than upon the definite hereditary factors, and that psychoses as such are not transmitted. Dr. Wright has outlined admirably well the intramural activities of the average state hospital and has given some mention to the social service department which acts as a liason between the hospital and the community.

We recognize in all this a vast improvement upon the old setup of the hospitals of even fifteen

or twenty years ago, but it seems to me the outstanding need today is for ever increasingly active educational programs for all groups and particularly the medical profession which for some reason has failed to show a wholesome attitude toward psychiatry. As I have said before, it seems to me this difficulty will be met by improved curricula in psychiatry in the medical schools of the country which, I think I am safe in predicting, will manifest itself in the very near future.

I am happy to have had the privilege of studying Dr. Wright's paper prior to his presentation today and also feel it is a privilege to have had the opportunity to discuss it.

NEARING THE LIMIT OF LONGEVITY

Some of the health experts are wondering if New Zealand is now nearing the top score attainable in longevity in our present state of medical knowledge and skill. It seems that the male infant born there can expect on an average, to live 65 years and the female to within six weeks of 68 years. This puts New Zealand in first place among all countries in the world. Of course, the question whether it is better to live a shorter time in America than a longer time in New Zealand does not enter into this particular discussion. The *Statistical Bulletin* of the Metropolitan Life Insurance Company informs us that the mortality in the first year of life among the white population of New Zealand is only 38.35 per 1,000 for males and has reached the exceedingly low figure of 25.48 for females. The corresponding figures for the white population of the United States in 1930 are 60.86 and 48.21. Perhaps nothing could testify more eloquently to the excellent health management in New Zealand than this low mortality among babies. For at that stage of life everything depends on proper

care of the mother and child. Nowhere along life's path can effort be expended with greater effect. Infant mortality is at best a high figure, from which any percentage curtailment means a large absolute gain. As the child grows older, it enters a zone of low mortality, with a minimum of not much over 1 per 1,000 per annum about age 10. The opportunities for improvement here are small, and can at best result in only slight saving. On the other hand, toward the late period of life, when mortality again mounts to high figures, the causes of death belong increasingly to a class against which we have far less efficient means of defense than those which have so successfully been brought to bear on mortality from the infectious diseases and the principal diseases of early infancy.

In view of these facts, it seems that we cannot look in the near future for the addition of many more years of life to the average already achieved by our fortunate contemporaries in the Antipodes.

POLIOMYELITIS IN CALIFORNIA

Doctors are being besieged by anxious parents who wish to know if it is safe to take their children to California, where an increase in the incidence of anterior poliomyelitis is reported in the Los Angeles area. The advice of the *Jour. Am. Med. Assoc.* is that "it is not considered safe to send a small child into the vicinity," for "the danger is definite and should not be assumed if it is avoidable." Moreover, we are warned, a child under six years of age falls within the most susceptible age group and for this reason would be subjected to a special hazard if taken

from a noninfected area into an infected area. It is, moreover, especially difficult to protect a child against contact with infantile paralysis, since the disease seems to be distributed by carriers, as are also scarlet fever and diphtheria, so that the child might become infected from a person who is apparently well. Epidemiology establishes the fact that infantile paralysis, like epidemic encephalitis, clears up with the coming of cold weather. In the Los Angeles area the first really cool weather may not be expected until November or December.

HE MERELY NEEDED A DOCTOR

A story to illustrate the need of the general practitioner is told by the editor of a medical journal in the Midwest. He found in his trip to the Cleveland meeting of the American Medical Association that everyone was talking about the general man, about how he has been getting the worst of it, and about what can be done to help him. Medical meetings give too much time to the specialists and laboratory men, thinks this observer, and the general man would be more interested in a conference where actual bedside experiences are exchanged. The story he relates was told by one of the heads of a famous clinic

some years ago at a meeting in Philadelphia: A patient had entered the clinic, and after some two weeks of observation a diagnosis had not been made. Then the patient died. The clinic head, desirous of knowing just what had been going on, went to the autopsy room just before leaving for Philadelphia. He inquired as to the findings and was advised that they were nil. He remarked that something must have been wrong and asked, "What was the cause of death?" The pathologist answered, "The man died of too many examinations; what he needed was a doctor!"

Anesthesia and Loyalty

Somewhere about five and twenty years ago physicians in a certain large institution (not the hospital or its superintendent) considered the practical results in anesthesia and found them wanting. Being exceedingly practical physicians, they thought only along immediately practical lines. Anesthesia by technicians (largely graduate nurses) came into being. The remote implications and results of anesthesia by technicians were, however, overlooked. These pioneer physicians, superb in their work and widespread in influence and associations, were quickly copied (the sheep quality of cerebral activity prevails among physicians as in the cloak-and-suit trade or the automobile industry). First, surgeons, then hospital managements embraced the idea for good and varying reasons, mostly interesting but not under discussion at this time. Gradually the licensed physician-anesthetist was replaced. In many Eastern hospitals, nurses, trained in the routine of inhalation anesthesia, have been substituted. Good routine results have prevailed in most instances.

Specialists in anesthesia have developed but slowly in number during the ascendancy and reign of this style. However, some

of these specialists and some physiologists, chemists, and pharmacologists have separately and together greatly enlarged the field of anesthesia by evolving new agents and new methods of administration. Local, regional, and spinal anesthetics are more used than formerly. The field is now a broad specialty, requiring as much general medical, clinical, and technical training as any of the specialties.

The work is, as it has always been, an element of the practice of medicine. Thus some physician (usually the operating surgeon) is directly civilly and legally responsible for the acts of the nurse-anesthetist. Indeed, for all the work done by thousands of technicians "to diagnose or treat," the Medical Practice Act holds a few physicians responsible. Can they afford to carry the load? The domain of medical practice has been largely eroded while the obligations, the responsibilities of physicians, have been inexorably increasing.

In 1933, the House of Delegates voted a brace of uncompromising resolutions concerning anesthesia, which insisted that physicians and dentists re-assume all practice of anesthesia. These resolutions were preceded by an explanatory preamble intelligible to any reader. The House of Delegates of 1934 re-affirmed these resolutions and ordered the New York State delegates to present them for the consideration of the American Medical Association. That said resolutions have caused discussion among our kind is well known. Most of the defenders of the *laissez faire* régime fail to consider any but routine inhalation anesthesia. On the other hand, many of those who condemn anesthesia by technicians present woefully limited arguments. We recommend the preamble of the resolutions to their attention.*

Recently a skilled surgeon in a famous city of the State at a public (not medical) meeting declared (according to press reports) "that the sponsors of the movement [against nurse anesthetists] are not inspired by altruistic interest in the welfare of the patient but by 'purely selfish motives.' The New York State Medical

* *New York State Journal of Medicine*, June 15, 1934, p. 553.

Society," he said, "is one of the organizations backing the ban on nurses." Also, "Most of the doctors administering anesthetics are 'misfits' who are simply waiting for something better to come along." He warned that anesthetics unskillfully administered by physicians without the necessary training would cause a sudden rise in the mortality rate among convalescent patients. Doctors, as a rule, do not give good anesthetics. "Certain dissatisfied elements in the medical profession maintain that the administering of anesthetics is the enterprise of doctors only. They do not persuade that their reasons for banning the nurse anesthetist are altruistic ones nor that the trained nurse does not properly administer anesthesia. They are simply seeking a law to prevent something. That's the fashion in this country at the present time."

This surgeon is a member of the Society whose resolution he publicly denounces. Why not protest to the Society before condemning its action? Had he taken the trouble to talk with State Society officers or committeemen, even though he cared not to attend State Society meetings, he would have learned much of which he seems (via press reports) to be ignorant. Does he recognize advances and elaborations in anesthesia? Or is he content to jog along in the trail blazed during his early days of training? Has he looked westward and observed progress in anesthesia there? Where are the specialists in anesthesia of the future to be trained? Does he know that some malpractice insurance may be void if death takes place under anesthesia not conducted by a licensed physician? Is it desirable to maintain the integrity of the Medical Practice Act? Indeed our violent confrère has much to learn about this subject before he will be justified in an attack upon his own State professional organization. Most of this physician's colleagues in the State have quite as much "altruistic interest in the welfare of the patient" as he can boast. Of this he has no monopoly and such a declaration as his smacks slightly of excessive self-adoration and self-praise. But in the main his disloyalty is the result of deficient understanding. The operator of an automobile who,

through ignorance, does damage is just as guilty of "reckless driving" as the expert driver whose aggressive disregard of rules results in accident.

This incident, of itself, is a trifling affair. Because it is an example of what happens frequently, it is *important*. Scientifically learned men sometimes allow themselves to be cajoled by laymen into attacking their colleagues. Lacking understanding of the larger part or the larger view of the subject they indulge in loose talk, and in order to thrill their hearers utter broad generalizations condemning many or all of their kind. This delights and encourages the enemies of modern scientific medicine who are the enemies of the people. We physicians are thinking and laboring first and always for our patients. Implications or bald statements to the contrary are indeed disloyal. Loyalty is based on understanding. If understanding could lead one to condemn something about our organization, then that would, in turn, be loyalty. However, the first attack should take place *within the organization*. The discussion there provoked would invariably be enlightening to all. Such external tirades as the one quoted are like the pebble thrown into a placid pool. Impulses are carried far in the widening circles activated by the cleavage. The JOURNAL deprecates public attacks upon our organization by a member who knows he has not complete information before he starts his denunciatory generalizations. Such performances are always vicious in their influence but most dangerous when they come from outstanding men of large accomplishment. *Responsibility increases directly in proportion to knowledge, gifts, and influence.*

Understanding has two phases: understanding of facts and their relationships, and understanding of other involved people. If we are painstaking in searching for facts, accurate in noting them, strictly fair in the interpretation and balancing of them, our conclusions will be just and probably right. If we discuss them among ourselves before addressing the public we reach the second stage of understanding. When understanding is complete we can choose between loyalty and disloyalty. One hundred to one it will be loyalty!

One on Darwin?

As we have seen world records fall again during the athletic meets in the past few weeks, we may not have realized that one of the defeated was none other than the great thinker whose work on the origin of species is in every scientific library. As we see our splendid young men and women walk the street, inches taller than their forbears, we may not have sensed the fact that they are turning the old scientific ideas topsy-turvy.

For the world-shaking theory of Darwin and Spencer was the Survival of the Fittest. The struggle for survival, they said, eliminated the weaklings, leaving the strongest who reproduced more strong ones, so that the continuous battle kept producing stronger and stronger specimens, while the feebler ones fell by the way and disappeared. That explained how the human race evolved from the animal kingdom and why the race is growing stronger and better all the time.

Fine. The entire scientific world accepted it as gospel. But, strangely enough, in recent years we have been going just contrary to its teachings. Instead of intensifying the battle, to bring out the strong ones in all their glorious supremacy, medical science has outdone itself and gone to all lengths to save and coddle everybody, strong and weak alike. Infantile diseases that used to sweep the babies off like flies have been simply abolished. The infant death rate has been cut in half. The struggle for existence has been reduced to a pillow fight. Babies that formerly would have taken a quick trip to the cemetery now grow up and take prizes in college.

Well, what is the result of this reckless disregard of Darwin's dictum? If he was right, we should have about now a world of invalids, cripples, crook-backs, and crocks of all descriptions. Instead of that, we have what is probably the finest display of health, strength, and beauty among our young people that the world has ever seen. Our young men can run faster, row faster, jump higher and farther, and throw weights farther than ever before known, and as for our young women, nothing ever done by the women of the past even comes into comparison.

It is not necessary to say that Darwin was wrong. It would be a brave critic indeed who would go to that length. But is it not possible to suggest that we have found another, perhaps a better, way to improve the race? The doctrine of the Survival of the Fittest would eliminate the weak. If they cannot stand the pace, let them perish. Better so. That was the gospel of Darwin and Spencer. The new gospel is an advance on that. Make the weak strong! That is what the medical profession are at, seven days a week, year in and year out. And the new gospel works!

Sir Christopher Wren said: "If you would see my monument, look around you!" He built churches. The modern physician can say: "If you would see my work, look around you!" And a world of health and happiness is his monument, and a monument to medicine's New Deal of survival and fitness for all.

A Study of 35,000 Malpractice Suits

Something like 4,000 suits a year, or over ten a day, are brought against the doctors in the United States for malpractice. This mere statement shows the gravity of the situation and gives point to an exhaustive study of the causes of these suits, made by two Massachusetts surgeons, Dr. Halbert G. Stetson, a former president of the Massachusetts Medical Society, and Dr. John E. Moran, who is associated with him in the County Hospital at Greenfield. They have obtained information from liability corporations and physicians on 35,000 cases, and publish their findings in the *New England Journal of Medicine* (Boston).

To come at once to the principal cause, however unpleasant it may be, they find that 60 per cent of the suits are due to "inopportune remarks" by subsequent attending physicians, slighting or slurring statements that suggest to the patient's mind that the first doctor blundered and that he can realize something from a lawsuit. These remarks may be almost involuntary or unintentional, or they may be charged with the venom of professional jealousy. They may be wordless. A lift of the eyebrow, a shrug of the shoulder, is

enough. Some informants put the proportion of suits due to these professional aspersions as high as 80 per cent of the total. A doctor may be unwittingly trapped into a criticism. A specialist, for instance, is visited by a patient he has never seen before, gives his opinion, and, months later, is summoned as a witness in a suit. A doctor is asked a hypothetical question by a lawyer friend. He answers offhand, and a little later finds he has to answer it before a jury. These are among the "inopportune remarks" that start litigation.

Worse, however, are the barbed criticisms made by physicians embittered by personal enmity, animosity, and professional jealousy. These men perhaps do not realize that they are fanning a fire that may burn their own fingers some day, for one suit kindles another, and, next time, they may find themselves brought to court and mulcted to the tune of hundreds or thousands of dollars. One informant put the number of suits due to "inopportune remarks" at 65 per cent—45 per cent incautious and 20 per cent "undoubtedly due to professional jealousy, self-assurance, and superiority psychology." The authors recall the statement of a famous (if mythical) old New York State resident, none other, in fact, than Rip Van Winkle, who said after one of Dame Van Winkle's outbursts of temper: "A tart tongue never mellows with age, and a sharp tongue is the only edged tool that grows keener with constant use." Volumes have been written on the mischief done by this unruly member, but evidently without making it much better.

Next, in order of importance, are the counterclaims brought because the physician is trying to collect his bill. Such suits, of course, are hardly avoidable, but the doctor can have his records in such good shape as to insure an iron-clad defense.

Fractures, it appears, cause a large number of malpractice suits. No less than 90 malpractice suits based on fractures were pending in Boston alone at one time. One investigator attributes 90 per cent of the fracture malpractice suits to the absence of x-rays, divided thus: diagnosis missed, 56 per cent; a complication overlooked, 18 per cent; malunion not recognized, 12 per cent; allegation by hostile practitioner

could not be refuted, 4 per cent. The remaining 10 per cent are laid to the adverse criticisms mentioned above.

How can these suits be avoided, or, if not avoided, successfully defended? First of all, the physician should keep an accurate and detailed record of his treatment of the patient, copies of prescriptions, x-ray pictures, all details of operations. The so-called "practical" nurses are often lax in making records, and the doctor should keep a watchful eye on them. Consultations are advisable when the case is serious and the family look like trouble-makers. Pathological examinations are a help, too. Consent should be secured before an operation, in writing if the character of the parties is at all dubious. The consent should cover unforeseen complications that may appear during the operation while the patient is under anesthesia. The writers have put in a nutshell the following five "best safeguards against malpractice": (1) A cautious tongue. (2) Proper use of the x-ray. (3) Accurate and complete records. (4) Adherence to the code of medical ethics and application of the Golden Rule in the care of patients who have been previously attended by another physician. (5) A knowledge of the accepted forms of treatment.

Doctors must not imagine, either, that their insurance relieves them from payment. The policy holder always pays the bill. If he does not believe it, let him read the experience of the New Haven Medical Association. Their insurance company in seven years expended \$44,597, while the amount deposited by the group with the company was only \$18,127. What happened? The company notified the Association that future payments must be four to six times more than they had previously paid! Note, too, that this increase fell not only upon the doctors who have been mistaken in their diagnosis and treatments, but equally upon those who let fall the acid drops of unkindly criticism. So justice has a way of attending to its own punishments in the long run and of administering its own bitter dose where it is needed. A much pleasanter medicine would be the prescription adopted in the hard-headed world of trade: "Boost, don't knock."

Medicolegal

LORENZ J. BROSNAN, Esq.
Counsel, Medical Society of the State of New York

Chiropractors—Illegal Practice of Medicine

The members of the medical profession have been for many years witnesses to the attempts of the chiropractors to secure the passage through the State Legislature of a bill which will give legal sanction to their practices. Fortunately their attempts to change the Medical Practice Act have thus far failed. Recently a different sort of attempt on the part of a chiropractor to gain the sanction of law through the courts has been thwarted in a case decided by one of our criminal courts a few weeks ago.*

A proceeding was instituted against a certain chiropractor in which he was charged with engaging in the practice of medicine without a license. The charges were that on certain specified occasions he had diagnosed and treated certain human ailments in accordance with the theory and methods of the art of chiropractic. The defendant made an application to the court to dismiss the charges on a number of specified grounds. Several of the grounds of his application were technical and of no particular general interest. However, the principal theory relied upon by the chiropractor was that the sections of the Education Law under which he was being prosecuted were unconstitutional. He claimed that the provisions of that law, which defined the practice of medicine and prescribe the requirements to be met before a person is entitled to practice, were in violation of the Fourteenth Amendment of the Federal Constitution, and also in violation of the New York State Constitution.

The particular sections he claimed to be applicable were that portion of Amendment Fourteen of the Federal Constitution which reads as follows:

"Nor shall any state deprive any person of life, liberty, or property, without due process of law; nor deny to any person within its jurisdiction the equal protection of the laws."

and also the language contained in Article 1, Section 6, of the State Constitution as follows:

"No person shall be * * * deprived of life, liberty or property without due process of law."

The court in passing upon his application summarized the chief contentions of the chiropractor as follows:

"Upon that question the argument is made by the defendant, who is a chiropractor, that there has been a revaluation of his art of healing since the Education Law was enacted so as to require the court to hold that decisions by Legislatures of this State since the enactment of that law in refusing to make a special classification for his type in the art of healing, has resulted in discrimination. He claims that changes in our social concepts, in our economic conditions, in our new attitude toward constitutional interpretation which today is based upon the sociological point of view rather than upon the legalistic theory, and new information concerning his method of treatment of disease, must and should impel the court to decide that the relevant provisions of the Education Law and the failure of the Legislature to classify his method of treatment has resulted in discrimination. He has marshalled in his brief a great many facts, data, statistics, information, testimony, etc., which he claims sustain this argument. He maintains that because of such facts and information, data, etc., the time has come when the court should say that the law is discriminatory because of the failure to make special provision for his type of healing. Substantially these facts are that chiropractic is now legally recognized in nearly every State of the Union; that scientific men have recognized its principles and its efficacy as a healing art; that thousands practice this art in most of the States of the Union where the same is regulated and permitted; that in this State a great number are practicing even though not regulated; that patients in great numbers are being treated and want to be treated by this method, having recognized the same as an efficient method in the treatment of the ills of the human body; that law today is interpreted in an attitude based upon changed social conditions rather than merely following prior decisions. Added to this is the claim that the many exceptions contained in the law permitting limited practice has resulted in discrimination; has opened the door to others while prohibiting the defendant."

In its opinion in ruling against the defendant's theories and arguments, the court stated in part the following:

"We must assume that all the facts and information and revaluations claimed by defendant appeared before the Legislature. We must also assume that there appeared before the Legislature other facts, namely, that the educational standards in the field of the treatment of the

* *People v. Lee*, 151 Misc. 431.

human body have been raised in the past three decades; that qualifications as to education, training, etc., are far greater today than they were when the law was enacted, and that year after year higher standards have been set up for those desiring to practice the art of healing, at least in New York State. It must have also appeared before the Legislature that the standards of education have been so elevated that it has become almost impossible to gain entrance into a medical school. It certainly appeared before the Legislature that the chiropractor claims to be able to diagnose and treat nearly all human ills. With such information and facts before the Legislature, it is conceivable that they had a reasonable belief in the existence of conditions which required the enactment of the present law and the refusal to grant a separate classification for chiropractic. If this court could say that the Legislature had no reasonable belief in the existence of facts which was the basis of its action or under no possible circumstances could the Legislature form such a belief, then would it be justified in declaring the law arbitrary and unreasonable. But enough appears to indicate that the Legislature did have a reasonable belief in the existence of facts which caused it to act as it did. It was within the province of the lawmakers to say to the defendant upon the facts appearing before them: 'You are practicing the art of healing; you claim to do exactly what the doctor of medicine does in the diagnosis and treatment of human disease and ailments; you claim that you can cure all manner and forms of disease, and even though you deny the germ origin of disease and believe that all ills originate with the impingement of nerves in the vertebrae, we demand that your preliminary qualifications and training should be the same as that which we require of the doctor of medicine. In other words, we say to you that you must have the same qualifications even though you have a different method in the treatment of disease, and even though you may never use some of the knowledge which you may acquire as a result of your preliminary training.'

In effect, that is all the Legislature has done through the present Education Law and its refusal to create a new classification for defendant. With such a decision on the part of the Legislature the courts cannot quarrel because there appears to be a reasonable basis for such action, namely, the reasonable belief in the existence of facts which required the enactment of the relevant provisions of the law. There appearing, therefore, a reasonable basis for the action of the Legislature, the court cannot hold that the relevant provisions are arbitrary or unreasonable. As the law stands today, it simply requires of the defendant that before he can practice his art of healing, he must comply with the same requirements as does the doctor of medicine. The refusal to amend the law to include defendant and give him a different classification than the doctor of medicine, based upon a training not as great as that required of the doctor of medicine, is no ground for declaring the present law unreasonable or discriminatory, especially if his claim be that he is doing exactly the same thing that the doctor of medicine is doing in diagnosing and curing disease even though by a different method. Whether the Legislature was wise in acting as it did upon

such facts is no concern of the court. We are only concerned with the proposition as to whether facts appeared before it that justified the conclusion arrived at.

The defendant claims that as the law stands today he is prohibited absolutely from practicing his profession. If to require him to have the same qualifications and training as is required of the doctor of medicine is prohibition, then the argument is sound, but the answer is found in the fact that the Legislature had a right to place the same preliminary requirements upon him as upon the medical doctor, and his refusal to comply with such requirements is the cause of the prohibition, rather than the specified requirements of the Legislature. *To claim that it is arbitrary and unreasonable to place him in the same class as the medical man, is not well founded if it appeared to the Legislature that there is not much distinction between what he claims he can do and what the doctor of medicine claims as to diagnosis and cure.* The only apparent differences are (1) as to the theory of the origin of disease, and (2) as to the method of cure.

The defendant further claims that the relevant sections of the Education Law having made a classification for osteopaths, dentists, chiroprodists, etc., and not having made any provision for him, has resulted in discrimination; that because the door has been opened by the Legislature to the osteopath and to others limited in the art of healing as to method, etc., that, therefore, he has been discriminated against, and for that reason the law is unconstitutional, but here again facts and conditions appeared before the Legislature indicating that there was a reasonable basis for the separate classifications made by the Legislature. It at least had a reasonable belief in the existence of these facts. In the case of the osteopath, while his practice is limited in method, the qualifications and preliminary training required of him are almost coextensive with that of the doctor of medicine, and there appears the further fact (in so far as that art of healing is concerned) that the osteopath is trained in schools approved by the Education Department of the State of New York in so far as its standards and curricula are concerned, while the schools of the chiropractic, because of limited curricula, are not recognized. There presumably appeared before the Legislature facts from which they could have arrived at the conclusion that the object desired, namely, proper treatment of human ailments, will not be prejudiced by letting in the osteopath because of the fact that he is trained in schools which require of him the study of those subjects which the medical doctor is required to study, and there must also have appeared before that body the fact that chiropractic schools do not provide for the same training.

If we can conceive of a state of facts showing a difference between the osteopath and the chiropractor, whether we agree with the facts or not, we are bound to hold that the law is reasonable and not discriminatory in its classifications; that such a state of facts can be conceived is apparent from the statements of facts in the briefs submitted to this court, namely, the method of preliminary training and qualifications, the first approved by the Education Department and the second apparently not.

It has been held time and time again that the power to classify in the adoption of police laws admits the exercise of a wide scope of discretion in the Legislature. *Only when there is no reasonable basis and it is purely arbitrary, may a classification be held to be unconstitutional. A classification having some reasonable basis does not offend merely because it is not made with any mathematical nicety or because in practice it results in some inequality.*"

The decision of the court is highly gratifying, and it is unquestionably the only correct and proper one. If the decision should be appealed from, we trust and believe that the Appellate Courts will promptly and without any hesitation affirm the ruling.

Loss of Eye Caused by Infection

A general practitioner was called to attend an 11-year-old child whom he found in bed with a marked swelling on the right side of the face, particularly about the maxillary sinus. The doctor examined her nostrils and found a swelling on the lateral side of the vestibule of the nostril. He prescribed Burrow's solution and advised the mother to apply it to the face and nose of the child as a wet dressing. The next day he examined her face again and found the swelling in her nose larger, although the face was no more swollen. The doctor determined the condition to be a furuncle in the nose. At that time there was no swelling in the region of the child's eyes and she made no complaint about her eyes. He called in another doctor to act as anesthetist and with a scalpel incised the furuncle after ethyl chloride anesthesia had been administered. A profuse discharge of pus was obtained. The doctor swabbed the incision with iodine and inserted iodoform packing. He advised the mother to continue with the wet dressings. The next day the child's condition was greatly improved. The doctor kept in touch with the patient's parents by telephone and learned that her condition was satisfactory until a week after the operation had been performed. At that time the doctor was told that the child's eye was affected. He called at the child's home and found the eye protruding with a large swelling below the eye.

The doctor diagnosed the condition to be an infection of the eye cavity which had been caused by the passage of pus from the maxillary sinus into the ethmoid sinus. He turned the case over immediately to an eye specialist who subsequently found it nec-

essary to remove the eye. The doctor who removed the eye determined that the infection that developed was a colon bacillus infection, and was therefore not connected with the first doctor's treatment.

An action was instituted to recover for alleged malpractice on the theory that the doctor had used dirty and unsterilized instruments in operating upon the child at its home, and had thereby set up the infection that subsequently caused the child to lose her eye. The case was ready for trial in its regular order on the calendar and was answered "ready" by the plaintiff's attorney. When the case was called for actual trial, however, neither the plaintiff's attorney nor any of the plaintiff's witnesses could be found. On motion of defendant's attorney the action was dismissed.

Treatment of Cat Bite

A 12-year-old girl was brought to the office of a general practitioner and the doctor was told that a week before the child had been bitten by a cat. He found that the little finger of her left hand was healed over by a small scab, but that the child was suffering from lymphangitis and swelling in her left armpit. He applied an antiseptic to her finger and ordered wet dressings on the finger and an ice bag under the left axilla. The doctor saw the child thereafter from time to time for about two weeks and the child kept improving during that time. However, after such improvement the glands suddenly became large and painful and quite hard. The doctor informed the child's parents that he might have to open up the glands, but that the condition was not at the time ripe for incision, and he directed the parents to continue the ice treatment. Before the doctor determined definitely whether or not an incision should be made, the patient was taken to another doctor who took the child to a hospital and drained an abscess which had developed. It seems that at the hospital injections of tetanus antitoxin were administered to the child, although there were no symptoms of tetanus.

Some time thereafter a malpractice action was instituted against the general practitioner who attended the patient and the principal charge made on behalf of the child was that the doctor had not administered tetanus antitoxin.

The case came on for trial before a

judge sitting without a jury. The plaintiff called as a witness the surgeon who operated on the child subsequently to the treatment rendered by the defendant, and he testified that the condition which he observed and treated was nothing more

than a case of lymphangitis running its ordinary course. After all the testimony had been put in by both sides, the court directed a verdict in favor of the doctor thereby exonerating him from the charge of malpractice.

The Anaemias.—By Janet M. Vaughan. Octavo of 248 pages, illustrated. New York and London, Oxford University Press, 1934. Cloth, 12/6.

BOOKS REVIEWED

The Physician's Art.—An Attempt to Expand John Locke's Fragment de Arte Medica. By Alexander G. Gibson. 12mo. of 237 pages. Oxford, The Clarendon Press, 1933. Cloth, \$3.00.

This delightful little book is, as the Author states, "an attempt to expand John Locke's fragment De Arte Medica." The first chapter consists of a brief account of Locke's leaning towards medicine, followed by a reprint of the fragment (1669), which is, indeed, a quaint document. There are seven other chapters and an index. The author has amplified the fragment in a manner well befitting the times in which we live. His remarks on art and science, diagnosis, prognosis, on treatment and the ethics and management of practice, on the doctor himself, and on optimism are opportune and appealing. To the younger physicians of to-day, this book should possess a very high value, to the older groups a real charm. It can be profitably read and re-read.

J. M. VAN COTT

Recent Advances in Vaccine and Serum Therapy.—By Alexander Fleming, and G. F. Petrie. Octavo of 463 pages. Philadelphia, P. Blakiston's Son & Company, 1934. Cloth, \$4.00.

This book is divided into two parts. Part 1 deals with serum therapy and Part 2 with vaccine therapy. The writers have reviewed the recent literature on serum and vaccine prophylaxis and therapy in a number of diseases and present the information thus gained in a series of short chapters. In each chapter they describe methods of preparation of serum or vaccine, dose and methods of administration, and analyze the results obtained by different workers. The diseases discussed include diphtheria, tetanus, gas gangrene,

scarlet fever, pneumonia, meningitis, virus diseases, typhoid, dysentery, cholera, pertussis, colitis, gonococcus infections and numerous other conditions.

The technical worker will find here much technical information and the clinician can obtain a wealth of data which will be valuable in deciding when and how to use this form of therapy.

E. B. SMITH

The Foundation of Psychology.—By Jared S. Moore, Ph. D., and Herbert Gurnee. Second Edition, revised. Octavo of 287 pages. Princeton, N. J., Princeton University Press, 1933. Cloth, \$3.00.

This book contains matter not usually found in the ordinary textbook on psychology, and it presupposes a previous knowledge on the subject. It cannot be recommended as light reading; but any person who wishes a review of the various schools of psychology will find within these pages a thorough-going discussion of the many theories of thought which have been advanced.

There are three parts: first, the various definitions or conceptions of psychology which have been suggested in the past and are being extended to-day with the aim of drawing synthetic and positive conclusions as to the merits of these various conceptions; second, the field of scientific psychology, its distinctiveness from metaphysics, on the one hand, and from physical and biological sciences, on the other; third, the postulates necessary for the construction of a scientific psychology with special attention paid to the problems of parallelism, psychical causation, and the subconscious. The discussion on the subconscious is of special value to any physicians who are interested in a clear understanding of medical psychology.

JAMES L. MCCARTNEY

RECENT ADVANCES IN THE TREATMENT OF
EPIDEMIC ENCEPHALITIS

JOSEPHINE B NEAL, MD

In charge of the Division of Applied Therapy, Department of Health, New York City, Executive Secretary of William J. Matheson Commission for Encephalitis Research

The treatment of epidemic encephalitis is as yet purely empiric. The causative agent has not been definitely proven. Of course, determination of the agent might not be of much help in therapy. This is certainly true in infantile paralysis, which is known through experimental transmission to be due to a specific filtrable virus. Moreover, the finding of a specific method of treatment need not wait on the determination of the cause. It was known that quinine was specific in malaria and mercury in syphilis long before the plasmodium of malaria or the *Spirochaeta pallida* was discovered. Certainly the effects of epidemic encephalitis are so terrible that finding a cure for this disease is one of the most challenging problems that confronts the medical profession.

An accurate appraisal of the value of any method of treatment of epidemic encephalitis is extremely difficult. If a therapeutic measure is used in the acute stage of the disease, two questions immediately arise: first, does it lower the case fatality, and secondly, does it lessen the possibility of the development of the chronic stage. The case fatality of acute epidemic encephalitis has varied greatly in different outbreaks and it is impossible to say whether or not it has ever been modified by any of the many methods of treatment that have been used. To prove the value of a remedial agent, it would need to be used on a large number of patients and the results compared with those of an untreated control group. The second question is answered with even more difficulty. A group of cases treated in the acute stage must be followed for years, and the percentage developing the chronic stage must be compared with a control group.

It is also difficult to estimate the value of any method of treatment in the chronic stage of epidemic encephalitis. Remissions and progressions develop for no apparent reason and last for considerable periods of time. New symptoms appear while others subside. Of course, if a therapeutic measure were found that abruptly halted the progress of symptoms or, better still, produced a marked and permanent regression of symptoms in all patients in the chronic stage, it would be easy to recognize its value. No such remedy has as yet been found.

One can hardly discuss the question of therapy of epidemic encephalitis without referring briefly to the problem of etiology. In general there have been three theories: first, a toxic disturbance of the central nervous system, secondly, a neurotropic strain of the green streptococcus, and thirdly, a filtrable virus. The third theory has by far the most followers and, until recently, it has been more or less taken for granted that there was only one filtrable virus involved. While the identity of no virus has been definitely proved, considerable weight is given to the claims of the neurotropic herpetic-like virus, isolated several times abroad and in two instances in this country by Gay and Holden.* Widely divergent opinions are held in regard to the etiology of encephalitis following various acute infections, particularly measles and vaccination. These forms of encephalitis do not differ in their acute manifestations from epidemic encephalitis, and some of the patients progress to a chronic stage. Moreover they

* Gay F P and Holden M. Further Evidence for the Presumed Herpetic Origin of Epidemic Encephalitis. *Trans. Assn. Amer. Phys.* 48 16, 1933.

were reported very rarely before epidemic encephalitis became prevalent and yet their clinical picture is certainly so striking that they could hardly have been overlooked.

In the summer of 1933 an unusually large outbreak of encephalitis occurred in St. Louis. The symptomatology of these patients followed quite exactly the pattern of the meningeal type of encephalitis that has always represented a varying percentage of our cases. The etiological agent of this epidemic has been very definitely proved to be a newly isolated filtrable virus, pathogenic for mice. Serological studies are being made in an effort to determine whether or not this virus is implicated in other outbreaks of encephalitis and also its possible relationship to other viruses.

The possibility that the disease known as epidemic encephalitis may be caused by two or possibly more viruses complicates still further the question of therapy, particularly so far as possible specific agents in the way of serums or vaccines are concerned.

My own experience in treating epidemic encephalitis dates back to the fall of 1918, when the first cases were diagnosed in New York City. Since that time the members of the division of applied therapy of the Health Department have seen nearly a thousand cases of acute encephalitis, most of which were diagnosed as epidemic encephalitis. As a rule, these patients were treated only by lumbar puncture and by symptomatic measures. The average case fatality has been roughly 25 per cent, but this has varied quite widely when estimated year by year.

In my work with the Matheson Commission for Encephalitis Research I have had occasion to review the innumerable methods that have been used in the treatment of epidemic encephalitis, both in the acute and chronic stage. I have also had the opportunity of observing at the Neurological Institute more than 700 patients, mostly in the chronic stage, many of whom had tried several lines of therapy. A fair percentage of these patients have remained under the care of the Matheson Commission and have been treated by methods which will be described later.

The methods used in treating the various stages of epidemic encephalitis include most of the drugs listed in the pharmacopeia, all kinds of vaccines and serums and all known methods of physical therapy and psychotherapy.

It would be useless and tiresome to attempt to review the innumerable methods of therapy that have been used. Many of them were apparently tried for no reason whatever. In other instances drugs or other means of therapy were employed for symptoms that may arise in the course of many diseases and therefore have no particular relation to encephalitis. However, many measures have been used in an effort to destroy the infectious agent and to alleviate the symptoms characteristic of encephalitis and the various complications sometimes arising directly due to this disease.

METHODS OF TREATMENT

The more important of these measures may be listed as follows:

1. METHODS FOR THE DESTRUCTION OF THE INFECTING AGENT.—These are:

A. Chemicals:

1. Acriflavine and other dyes.
2. Salicylates.
3. Iodine preparations.
4. Colloidal metals.
5. Arsenicals, including arsphenamine preparations.
6. Mercury derivatives, including mercuriochrome—220 soluble.

B. Production of febrile reactions:

1. Numerous nonspecific proteins.
2. "Fixation abscess."
3. Malarial inoculations.
4. African recurrent fever.
5. Fever-producing baths.

C. Serums:

1. Convalescent serum.
2. Rosenow's encephalitis antistreptococcus serum.
3. Gay's herpes hyperimmune rabbit serum.

D. Vaccines:

1. Levaditi's herpes recovered rabbit brain vaccine.
2. Gay's herpes hyperimmune rabbit brain vaccine.
3. Gay's formalized herpes virus.
4. Rosenow's streptococcus vaccine for encephalitis.
5. Stewart's Pfeiffer bacillus vaccine.

Since it is now generally believed that the chronic stage of the disease is caused by the continued activity of the infecting agent, measures aimed at the destruction of this agent would be applicable at all stages. It is unnecessary to state that most of these types of treatment have yielded results that have been unconvincing, when applied to a fairly large number of cases. Of course, an apparently striking effect is occasionally reported, but those of us who have observed large numbers of patients, particularly in the acute

stage, have seen unexpected recoveries when only lumbar puncture and symptomatic treatment were used. I would be inclined to rate most of the methods of treatment under *A* and *B* as of little or no value, and malarial inoculations as positively dangerous.

In considering *C*, the use of convalescent serum seems particularly unjustified in view of the fact that so many patients fail to produce sufficient antibodies to check the course of the disease in themselves. Moreover, if it is assumed that the disease is caused by a neurotropic strain of the herpes virus, it is important to note that Gay and Holden have shown that these patients are actually more deficient than the average in antibodies against the herpes virus. It would be a difficult task to select donors whose recovery was really assured.

Rosenow's encephalitis antistreptococcus serum would be justified only on the ground that a neurotropic streptococcus is the cause of encephalitis. The followers of this theory are comparatively few. The results published of its effects are not well controlled.

On the theory that encephalitis may be due to a neurotropic strain of an herpetic-like virus, Gay's herpes hyperimmune rabbit serum has been used intramuscularly on about 25 of the most critically ill patients in the acute stage, and on a few patients in the chronic stage of encephalitis. In several instances quite spectacular recoveries have followed the use of this serum, and the case fatality has been lower than in a control group of patients in an apparently equally serious condition. However, unexpected recoveries do take place in patients not receiving possibly specific treatment and the number is too small to admit of definite conclusions.

We have had more experience in the use of vaccines. In planning the study of treatment, the Matheson Commission was confronted with two main theories in regard to the etiology of epidemic encephalitis: that it might be a form of the herpes virus, as claimed by Levaditi and others; or that it might be a neurotropic form of the *Streptococcus viridans*, as claimed by Rosenow and by Evans and Freeman.

It was therefore planned to carry out treatment by measures that might be specific for these two possible etiologic agents, namely Rosenow's encephalitis antistreptococcus serum and vaccine and Levaditi's rabbit brain vaccine. Levaditi's vaccine

was prepared by injecting his neurotropic herpes virus *C*, originally obtained from a case of encephalitis, intracerebrally into a group of rabbits, using such a dose that a part of the rabbits died and the remainder recovered after showing symptoms of encephalitis. The brains of the rabbits that recovered were emulsified, and after sterility tests were used as a vaccine. The vaccine was first prepared for us in Dr Gay's laboratory from a strain sent to him by Levaditi. In a short time, however, the strain lost its virulence so that none of the rabbits thus given injections died. After some experiments, Dr Gay devised a method of immunizing rabbits with a dermatotropic strain of herpes virus. These rabbits were then tested for immunity by the repeated intracerebral injection of multiple lethal doses of a strain of herpes virus isolated by Perdrau from a case of encephalitis. The brains of rabbits found to be immune were used to make a vaccine that Dr Gay has designated as the hyperimmune rabbit brain vaccine. These rabbits were also bled, and the serum was used in the treatment of patients with acute encephalitis.

During the past year we have been using a vaccine prepared by Drs Gay and Holden consisting of a formalized herpes virus. They have shown that in rabbits the formalized virus stimulates the production of antibodies much more regularly than does the hyperimmune rabbit brain vaccine.

Dr Rosenow has been generous in supplying us with his streptococcus vaccine for the group of patients treated by his method.

Space does not permit a detailed account of the manner in which the study by the Matheson Commission has been carried out. This has been described in a paper by Dr Inez A. Bentley and myself*. I may say in a general way that at the beginning of the work control groups were maintained using for the most part a vaccine consisting of normal rabbit brain. Although no one who was giving the vaccines or making the reexamination knew which was the hyperimmune vaccine and which was the control at the end of a year it was decided that the percentage of improvement was much greater in the group receiving the hyperimmune vaccine.

* Neal J. B. and Bentley I. A. The Treatment of Epidemic Encephalitis. *Arch. Neurol. and Psychiat.* 28: 897, 1932.

For humane reasons it seemed impossible to continue giving these patients the normal rabbit brain vaccine and they were transferred.

The hyperimmune vaccine and more recently the formalized virus has been given to patients in both the acute and chronic stages. It is administered intramuscularly in doses up to 4 c.c. and is given over a period of about eighteen weeks, followed by a rest period of six weeks to two months.

Approximately 28 patients have been treated in the acute stage by the vaccine. The case fatality has been lower than in the control group of patients not receiving vaccine. In general we use the serum for the patients who seem most seriously ill and the vaccine for those in which the attack seems milder. We do not believe that the number of patients treated is sufficiently large for us to draw definite conclusions in regard to the value of the vaccine. However, we are examining at intervals the patients treated in the acute stage with vaccine, serum, or in some instances, serum followed by vaccine, and in time we should have definite information in regard to the effect of early treatment on the development of the chronic stage. So far the results seem encouraging.

We have treated roughly 500 patients in the chronic stage using the rabbit brain vaccines, already described, and Rosenow's streptococcus vaccine. These patients have been under treatment for periods varying from a few months to nearly five years.

Without giving too many details, it may be stated that the group of patients receiving Gay's hyperimmune rabbit brain vaccine has shown a far greater percentage of improvement than has the group receiving Rosenow's vaccine. A small group treated for a year or less with the new formalized virus vaccine has now by far the best record, but too short a time has elapsed to enable us to estimate its value.

A very few patients under both Gay's vaccine and Rosenow's vaccine have shown really remarkable improvement. But we knew that these remissions may occur without treatment of a possibly specific nature.

Rosenow's vaccine may conceivably act in any one of three ways. If the disease is due to the neurotropic *Streptococcus viridans*, it may have a specific action. On the other hand, it may act favorably on any focal infections which are present in

so many of these patients, thereby improving the general health of the patient and lessening a possible toxic effect from the focal infections or the central nervous system. Finally, it may act simply as a foreign protein.

The only statements that can safely be made in regard to the results of treatment of encephalitis with a vaccine against the neurotropic herpes virus are that when used in the chronic stage, the results are distinctly better than when Rosenow's streptococcic vaccine was used. Also that when used in the acute stage, the case fatality seems to be lowered and there is some evidence to indicate that the development of the chronic stage may be averted. The inconclusiveness of any of these statements must be emphasized.

II. METHODS FOR MODIFYING THE COURSE OF THE DISEASE BY REDUCING INTRACRANIAL PRESSURE.—These consist in:

1. Hypertonic dextrose solution intravenously.
2. Hypertonic iodide solution intravenously.
3. Lumbar puncture.

Beneficial results have been obtained by all these methods in certain cases. The hypertonic dextrose solution certainly is valuable in building up depleted patients and in improving the action of the heart as well as in decreasing intracranial pressure. The action of the iodides is not so definite.

Forced spinal drainage has not been used on a sufficiently large number of patients to warrant any statement as to its value.

III. METHODS FOR THE CONTROL OF SYMPTOMS.—These include:

- A. Drugs:
 1. Duboisine, scopolamine, stramonium, and atropine.
 2. Bulbocapnine.
 3. Ephedrine sulphate.
 4. Sedatives, hypnotics, and analgesics, such as phenobarbital, bromides, amytal, chloral hydrate, etc.
- B. Endocrine therapy.

The various symptoms for which these drugs are used are too well known to require discussion.

Hyoscine, stramonium, and allied preparations often bring temporary relief in tremor, rigidity, and other manifestations of the parkinsonian syndrome. It has been our experience that patients taking these drugs over a long period have frequently increased the dosage to a point where toxic

effects were obtained. It sometimes happens that cumulative effects result even when the dose is small. Often it has been difficult to persuade the patient to reduce the dose, and sudden withdrawal of the drug is dangerous. That these drugs are habit-forming does not seem to be generally appreciated. We strongly deprecate the routine use of these drugs at clinics where patients are not under close medical supervision.

Atropine preparations have been useful in our experience in controlling sialorrhea, and they have not seemed to be habit-forming. We have not been able to duplicate in our patients the extraordinary improvement that has been reported in this country and abroad by the use of atropine sulphate in gradually increasing doses until 15 to 20 minims of an 0.5 per cent solution is given three times a day.

The use of bulbocapnine has been largely discontinued because of its toxic effects.

Ephedrine sulphate has been recommended for narcolepsy, but it has not been used in a sufficient number of cases to draw definite conclusions as to its value.

Oculogyric crises have been treated with a measure of success by the atropine group, by intravenous injection of a 10 per cent solution of calcium chloride, by epinephrine, by chloral hydrate, and by paraldehyde. We have not tried all of these measures.

In treating the patients who were immediately under our control we have avoided prescribing drugs of the scopalamine group and have endeavored to persuade those patients who were already taking them to diminish the dose or to eliminate them altogether.

IV. METHODS FOR BUILDING OF GENERAL RESISTANCE, HEALTH, AND MORALE. —These consist in:

- A. General hygienic measures, as diet, rest, and proper elimination.
- B. Removal of foci of infection.
- C. Tonics:
 1. Sodium cacodylate.
 2. Iron preparations.
 3. Strychnia.
 4. Other tonics as indicated.
- D. Physical therapy:
 1. Hydrotherapy.
 2. Electrotherapy, including diathermy.
 3. Roentgen treatment.
 4. Massage.
 5. Graduated exercise and reëducation of muscles.
- E. Occupational therapy.
- F. Psychotherapy.

General hygienic measures are of great importance at all stages of the disease, and especially during the acute stage. A prolonged period of complete rest is essential even in seemingly mild cases.

While we do not hold with those who believe that encephalitis is caused by toxins elaborated by focal infections, we do think that patients with encephalitis are adversely affected by these toxins. A special effort has been made to have foci of infection removed or treated.

Sodium cacodylate is highly recommended, especially in the subacute and chronic stages of the disease. It is given in large doses, either subcutaneously or intravenously.

Strychnia have been used with success in asthenic patients.

The value and methods of the more common forms of physical therapy are too well known to require comment. It may be noted that the improvement occasionally following roentgen treatment of the head was stated by von Economo to be due probably to the vasodilator effect of the irradiation and the subsequent hyperemia of the atrophic basal ganglia. A similar effect may be produced by diathermy.

It is most important to combat by every possible means the discouragement that patients suffering from chronic epidemic encephalitis are bound to feel. To this end patients should be urged to interest themselves in suitable forms of occupation, in games, and in other methods of entertainment. Fatigue must always be avoided, but exercise within the limits of their capacity is essential.

Every effort should be made to encourage a spirit of optimism and courage, for the will to recover, or the lack of it, plays no small part in the progress in most cases. This is a practical form of psychotherapy that every physician can use. In certain instances patients suffering from physical symptoms in a large measure due to mental conflicts are reported to have been improved by psychoanalysis or hypnosis.

In closing, I repeat that finding a cure for epidemic encephalitis is one of the most challenging problems that confronts the medical profession. If this is met with optimism and courage, we cannot doubt that medical science will eventually add this disease to the long list over which it has triumphed.

A FIVE-YEAR CLINICAL STUDY OF THE PROPHYLACTIC VALUE OF ANTIRACHITIC AGENTS

An Analysis of 948 Cases

ADOLPH G. DE SANCTIS, M.D., and JOHN DORSEY CRAIG, M.D.

From the Pediatric Department of the Postgraduate Medical School and Hospital of Columbia University, New York

This study consists of a critical analysis of 948 cases who received various antirachitic agents over a five-year period. Preliminary reports on this same study were published by us in 1930¹ and 1931,² respectively.

THE PRODUCTS AND THEIR DOSAGE USED IN THE CLINICAL STUDY.—The infants were divided into eight groups as follows:

1. Those given cod liver oil in liquid form—3 teaspoonfuls daily (8032 U.S.P.X. units of vitamin A and 3,057 A.D.M.A. units of vitamin D)—different cod liver oils used vary somewhat in unitage of vitamins A and D).

2. Those given irradiated ergosterol (viosterol) 100 X, 10 drops, daily (7,300 A.D.M.A. units of vitamin D, no A units).

3. Those given irradiated ergosterol (viosterol) 250 X, 10 drops daily (18,000 A.D.M.A. units of vitamin D, no A units).

4. Those given irradiated ergosterol (viosterol) 500 X, 10 drops daily (36,000 A.D.M.A. units of vitamin D, no A units).

5. Those given cod liver oil concentrate in tablet form, 3 tablets daily (tablets first contained 2,250 A units and 300 D units, those used later contained 6,300 A units and 1,500 D units).

6. Those given cod liver oil concentrate in liquid form, 10 drops a day (7,668 A units and 1,500 A.D.M.A. D units).

7. Those given provitamin A alone in liquid form through the use of carotene, 20 drops daily (3,500 A units).

8. Those given provitamin A and vitamin D—carotene in liquid form mixed with equal parts of ergosterol, 500 D (viosterol), and administered 20 drops daily, *i. e.*, 10 drops of viosterol and 10 drops of carotene (36,000 A.D.M.A. units of vitamin D and 1,750 U.S.P.X. vitamin A units).

In our preliminary reports^{1,2} on this study, we showed that as many as ten times the number of D units did not protect the infant as well against rickets when

given in the pure form (viosterol, D alone) as when given in cod liver oil either in liquid or concentrate tablet form. Concluding that rickets are not due to a deficiency of vitamin D alone, but that vitamin A and possibly other factors play an important part in this disease, groups 7 and 8 were added to substantiate these conclusions.

Several good grades of cod liver oil were used. A reputable firm furnished the 100 X, 25 D, and 500 X irradiated ergosterol solutions used. The cod liver oil concentrate in table form is one accepted by the Council on Pharmacy and Chemistry of the American Medical Association. The cod liver oil concentrate in liquid form was prepared for us to use in this clinical experiment. Provitamin A in the form of carotene was furnished by the company which supplied us with the viosterol solutions.

The potencies are given in U.S.P.X. vitamin A units and A.D.M.A. vitamin D units. The U.S.P. Revision Committee is revising the vitamin standards for cod liver oil and the new units which will be known as "U.S.P.X.—Revised 1934" will be identical with the corresponding International units as defined and adapted by the Conference of Vitamin Standard of the Permanent Commission on Biological Standardization of the League of Nations, in June, 1931.

According to the U.S.P. Revision Committee:

One U.S.P.X., Sherman and A.D.M.A. unit of vitamin A equals 1.4 International or new U.S.P.X. 1934 units.

One Steenbäck unit of vitamin D equals 2.7 International or New U.S.P. units or 8.77 A.D.M.A. vitamin D units.

One International or U.S.P. revised 1934 unit of vitamin D equals 3.25 A.D.M.A. units.

CONDITIONS OF THE STUDY.—All infants who received a smaller amount or who did not receive the stated amount daily for at

least three months were not included in this study. This necessarily eliminated approximately half of the number of cases studied. All told, some 2,000 cases were critically analyzed. No premature infants were used. It must be borne in mind that all infants in the various groups were started on an antirachitic agent at approximately the same age, gained at the normal rate, and were kept under observation for approximately the same length of time and during the same seasons of the year, also that the series did not include any infants who were gaining extremely rapidly. While various types of feeding were used in all groups, apparently these different methods of feeding had no influence on the results observed. In brief, the infants were all similar in age and dietary treatment and in rate of growth.

INTERPRETATION OF CLINICAL OBSERVATIONS—It is conceded that in the interpretation of clinical observations there may be a great variation of opinion as to what constitutes clinical rickets. Whenever there was any doubt in interpretation, the case was eliminated. The final examinations were made by at least two well trained physicians independently of each other, and their observations were charted.

The so called physiological beading so frequently referred to in the literature occurring in early infancy was enough to cause elimination of the infant. The congenital and presumably physiologic craniotabes occurring in early infancy and stressed by many authors was excluded. Many of our cases developed craniotabes approximately between the third and fifth month and cleared spontaneously showing no other rachitic manifestation. These cases are not considered as rickets.

As clinical evidence of rickets, we included marked occipital craniotabes, moderate and marked costochondral beading, grove and flaring of the ribs, epiphyseal enlargement, bowing and spasmophilia. Unless two of these manifestations existed at the same time, however, the case was not considered as having clinical rickets. Again, as all of these infants were under observation for at least three months or more, the final examination was made necessarily at an age at which so called physiologic beading and craniotabes would not be present.

A larger incidence of bowing is seen in some groups by virtue of their having been observed over a longer length of time.

A general statement can be made that from 25 to 30 per cent of infants not receiving antirachitic agents develop clinical rickets. In 469 babies under one year of age, Wilson found that 121, or nearly 25 per cent, developed clinical rickets when no antirachitic agent was given. Moore and Dennis,⁶ in 120 cases found 28 (about 23 per cent) to be unprotected. May Wilson, Barenberg, and Bloomberg,³ De Buys and others found an even higher incidence of unprotected cases. The incidence of rickets in infants not receiving antirachitic agent is but slightly higher than that in our group of infants who received viosterol.

No harmful effects or symptoms or signs of hypercalcemia were noted in any of the cases.

Calcium and phosphorus blood determination were not made except in a few cases because of the refusal of the parents to permit the withdrawal of blood. However, as Hess⁴ pointed out, the level of inorganic phosphate in the blood is not as infallible a criterion of rickets as heretofore believed. He states that the fact that the cure of rickets is independent of the concentration of the phosphate in the blood, indicates that variation of this constituent cannot be regarded as an essential or inherent feature in the pathogenesis of the healing of this disorder. He also emphasized the fact that the product of calcium times the phosphorus concentration in the blood is not a reliable indicator as to whether or not active rickets are present.

The prophylactic dosage of antirachitic substances seems fairly well established for cod liver oil at from 1,500 to 2,000 A D M A rat units daily of vitamin D.¹⁰ However, as has been shown by us^{1,2} and others¹¹ when vitamin D is given in other forms it requires up to ten times the dosage of vitamin D expressed in rat units to approach the prophylactic antirachitic results obtained by the use of cod liver oil. Barnes,¹² in 1933, tested clinically a corn emulsion of cod liver oil concentrate, giving from 4,000 to 12,000 A D M A units of vitamin D and 1,000 to 3,000 U S P X vitamin A units daily. He showed that healing was very rapid in all cases which was borne out by the return of the blood

calcium and phosphorus to normal in two weeks or less and a rapid increase in the strength and activity of the child. Roentgenograms show rapid calcification.

SUMMARY OF FINDINGS

1. Cod liver oil in liquid form in a dosage of three teaspoonfuls a day (3,057-6,642 A.D.M.A. units of vitamin D and 8032-13,290 U. S. P. X. vitamin A units) prevented rickets in 97 per cent of one hundred cases studied.

2. Viosterol 100 X given in 10-drop daily doses (7,300 A.D.M.A. units of vitamin D, no A Units) prevented rickets in 77 per cent of the 123 cases studied.

3. Viosterol, 250 X given in 10-drop daily doses (18,000 units of vitamin D, no A units), prevented rickets in 81.5 of the 128 cases studied.

4. Viosterol 500 X given in 10-drop daily doses (36,000 units of vitamin D, no A units) prevented rickets in 76.8 per cent of the 156 cases studied.

5. Cod liver oil concentrate in tablet form given in doses of 3 tablets daily (1,500 A.D.M.A. units of vitamin D and 6,300 U.S.P.X. vitamin A units) prevented rickets in 92 per cent of the 142 cases studied.

6. Cod liver oil concentrate in liquid form, 10 drops daily (7,668 A units and 1,500 D units) prevented rickets in 78.5 per cent of the 99 cases studied. We cannot explain why cod liver oil concentrate in tablet form gave almost the same degree of protection as cod liver oil while the concentrate in oil solution (made by the same concern that made the tablet concentrate) did not. Possibly this is due to a lack of stability of the vitamins in the oil solution.

7. Provitamin A in the form of liquid carotene given in 20-drop daily doses (3,500 A units) prevented rickets in 79.5 per cent of the 99 cases studied.

8. Viosterol 500 X and vitamin A in the form of liquid carotene (36,000 A.D.M.A. units of vitamin D and 1,750 U.S.P.X. vitamin A units) given in 10-drop daily doses of each prevented rickets in 87.5 per cent of the 101 cases studied.

CONCLUSIONS

1. Cod liver oil in liquid form—three teaspoonfuls daily (8,032 to 13,000 U.S.P.X. units of vitamin A and 3,057 A.D.M.A.

vitamin D units—gives almost complete protection against rickets.

2. Cod liver oil concentrate in tablet form—3 tablets a day (6,300 U.S.P.X. units of vitamin A and 1,500 A.D.M.A. vitamin D units—gives almost the same degree of protection.

3. Viosterol in 100 X, 250 X and 500 X (7,300 to 36,000 vitamin D units, no A units) gives only slight protection.

4. Carotene (3,500 A units, no D units) does not give protection.

5. The addition of carotene to 500 X viosterol (36,000 D units and 1,750 A units) gives almost 90 per cent protection. It is significant that the addition of provitamin A decidedly increases the degree of protection.

6. We are yet of the opinion that rickets are not due to a deficiency of vitamin D alone, but that vitamin A is an important factor in this disease. Because of the fact that even ten times as many D units in the form of viosterol do not give the same protection as cod liver oil, it is fair to assume that the D factors in viosterol and cod liver oil are not identical.

BONE TUMORS AND ALLIED CONDITIONS

JAMES MORLEY HITZROT, M.D.

New York City

In order to understand the formation, location, and development of bone tumors, it is necessary to refer to the embryological development of bone. All the elements of bone, fibrous, cartilaginous, and osseous, are derived from a primitive connective tissue. In the skull this connective tissue undergoes a direct transition into bone (membranous bone formation). In the other bones the transition is from connective tissue to cartilage to bone, that is, calcification occurs in the adult cartilage cells to form the finished bone. In the long bones, in the early stages of their formation, a portion of the cortex is formed by a direct transition from the connective tissue of the primitive periosteum into bone.

A condition not unlike the above is found in the repair processes in bone, as anyone of the transition stages may be seen, and frequently, where one type of cells, young connective tissue or young cartilage cell preponderates, the condition may be confused histologically with a tumor growth.

A misconception exists about adult bone, namely, that it is a fixed product undergoing little or no change under ordinary conditions and that its chief function is a structural one. On the contrary, bone is a very active structure differing from connective tissue and other tissues in its stability, due to the calcareous matrix. This stored-up calcium, however, is drawn upon or augmented by conditions in the body in which calcium is metabolized for bodily needs. The control of this calcium metabolism is probably under the influence of the parathyroids and is drawn upon or increased in the bones by these glands by a mechanism as yet not definitely understood. This is perhaps best seen in pathological conditions in the parathyroids, especially tumors with hyperparathyroidism and a progressive decalcification of the bones. Aside from these essentially pathological conditions the normal bone is constantly undergoing changes not easily demonstrated, in which the calcium supply to the body is kept at a normal level.

The medullary portion of bone, the bone

marrow, is also an active organ, among its functions being blood formation including the red cell, the white cell, and the platelets, and diseases of this structure affect the growth and character of the cortical bone in easily demonstrable ways (erythroblastic anemia).

There is also a definite predisposition to bone tumor formation in the growing bone, which results from the growth changes in the young cartilage cell especially where the process of calcification is more complicated or delayed in its development.

Geschickter and Copeland¹ state: "It is delayed developmental steps in the primitive connective tissue of the skeleton and in conjunction with subsequent histogenic steps, after the cartilage has been formed, that practically all primary bone tumors occur." Their publication is worthy of careful study by anyone interested in the study of bone tumors.

That bone tumors arise in the embryological tissue which precedes normal bone is, the author believes, indisputable. Just how and just what produces these alterations or reversions in growths is not so easily stated.

CLASSIFICATION OF BONE TUMORS

Many classifications of bone tumors exist based upon histological, clinical, radiographic, or other methods. All are incomplete and necessarily so since there is much about normal as well as pathological bone which is not as yet completely understood.

CLASSIFICATION OF BONE TUMORS—AMERICAN COLLEGE OF SURGEONS

- I. Metastatic.
- II. Periosteal fibrosarcoma.
- III. Osteogenic tumors.
 - A. Benign.
 1. Exostosis
 2. Osteoma.
 3. Chondroma.
 4. Fibroma.
 - B. Malignant (sarcoma).
 1. Anatomic types.
 - a. Medullary and subperiosteal.
 - b. Periosteal.
 - c. Sclerosing.
 - d. Telangiectatic.
 2. Undifferentiated sarcoma.

IV. Inflammatory conditions simulating tumors.

1. Osteoperiostitis—traumatic, syphilitic, infectious.
2. Osteitis fibrosa.

V. Giant cell tumor.

VI. Angioma.

1. Benign.
2. Malignant (angiosarcoma).

VII. Ewing's tumor.

VIII. Myeloma.

Geschickter and Copeland (loc. cit.) give the following classification:

I. Tumors related to osteogenesis.

A. Tumors derived from precartilaginous connective tissue.

1. Osteochondroma or benign exostosis.
2. Chondroma or benign chondromyxoma.
3. Primary chondromyxosarcoma.
4. Secondary chondromyxosarcoma.
5. Osteoblastic osteogenic sarcoma.

B. Tumors related to subsequent cartilaginous growth.

1. Chondroblastic sarcoma.
2. Osteolytic osteogenic sarcoma.
3. Bone cyst and osteitis fibrosa.
4. Benign giant cell tumor.

II. Tumors of non-osseous origin.

1. Primary lymphoma of bone (endothelial myeloma of Ewing).
2. Multiple myeloma.
3. Metastatic carcinoma.
4. Fibrosarcoma and neurogenic sarcoma.

Clinically they may be classified as benign, malignant, doubtful. In the first two the diagnosis clinically easily separates them into definite categories. In the last group, many differences of opinion may occur, and this will be referred to later in the remarks under diagnosis.

From the x-ray standpoint, a classification based upon the findings in the radiograph gives a classification based upon these findings. The essential facts to be noted are:

1. Location—periosteal, cortical, or medullary, involvement of the epiphysis or diaphysis.
2. Bone-productive, bone-destructive, bone atrophy, sclerosing or eroding tumors.
Bone-invading, not bone-invading.
Bone-expansive tumors.
3. Number of bone growths—solitary or multiple.

From these findings various classifications and deductions have been made and the varying x-ray changes are of the greatest diagnostic value, since the varying changes produced in the bone are indicative of the character of the tumor.

ETIOLOGY

In the osteochondromas, hereditary or congenital causes play an important part due to the variation in the periosteal apertures through which bony protuberances arise normally. Inflammation plays a part in the irritation of the cartilage cells normally present in the attachment of tendons to bone.

Injury may play a part in disturbing the normal balance in bone formation and perhaps produce changes in the osteogenic zones, especially changes in the rate of proliferation in the adjacent precartilaginous tissue which disturbance may lead to tumor formation. The relation of injury to bone tumor formation is worthy of careful analysis and the relation of the trauma, in time, to the appearance of the growth should be carefully noted. An indefinite history of trauma can nearly always be elicited and the comparison of the changes which have already taken place in the bone at the time it is examined may be entirely too remote or the changes may be too great to be given any weight in the given case. This point is of special importance since the Industrial Legislation, under the Workmen's Compensation Act, will require medical opinion as to the relation of the given trauma to bone tumor formation in specific instances, and a careless analysis of the trauma in its relation to the bone growth and its development and character as related to the injury in question may lead to grave errors either way. That trauma plays some part in the formation of bone tumors cannot be specifically denied, yet it can scarcely be conceded that a single definite trauma is the essential cause of the tumor formation. Slight injuries produce fractures in bones already the seat of disease *i.e.*, pathological fractures, but the tumor itself antedates such trauma and is not the cause of that tumor.

GENERAL CLINICAL FEATURES:

- Age:* Bone cysts occur most commonly before the twentieth year.
Giant cell tumor between twenty and thirty, as a variation may rarely occur at any age.
There is no common age for the periosteal and central sarcoma, but as a rule they occur in young individuals.
Metastatic tumors occur in middle to old age.
Myeloma occurs in adult life and is rare in the young.
Ewing's tumor—diffuse endothelioma of bone—occurs before twenty-five in the vast majority of cases.

Pain Benign Onset insidious, a variable factor and dependent on the formation of bursa, pressure on adjacent structures, or injuries to the tumor

Malignant Onset more definite, pain more marked and is more marked in the patient's story. It is more persistent, does not disappear with rest, is increased by use. Occasionally it may be very acute with fever, sweats and leukocytosis and run an acute course

Duration Benign Long course, trouble exists for months or years

Malignant Short course, patient dates trouble in weeks

Character of Growth Benign Slow, swelling increases gradually over a long period. Swelling usually precedes pain, no rapid swelling

Malignant Sudden appearance of swelling which increases more or less rapidly. Pain precedes swelling and increases with swelling

Disability Benign Usually slight, some interference with joint function some lameness after use which subsides with rest

Malignant Slight at first but increases rapidly with distinct lameness, both increased by use. Does not disappear after rest

Spontaneous fracture is common and Blood good considers it diagnostic in bone cysts. Occurs as a late result of malignant growths in bone

Skin Changes Glossiness of the skin enlargement of the superficial vessels pulsation of the tumor are late symptoms. Likewise, cough, chest involvement, and metastasis are late results

DIAGNOSIS

In the diagnosis of any bone tumor certain general rules of procedure are of value. Pain in the course of a long bone or any unexplainable pain in any region of the skeleton should be examined by the x-ray and the findings thus obtained studied in conjunction with the other clinical findings by the roentgenologist and the clinician

Every malignant tumor of bone and every doubtful tumor should have an x-ray examination of the chest. Evidences of lung involvement will have a very definite effect upon our clinical procedure in the handling of the given case. X-ray examination of the chest is also a necessary procedure in the follow-up of malignant bone disease

Every patient with a bone tumor should have a Wassermann or similar blood test. In doubtful cases Bloodgood believes a therapeutic test by salvarsan and the iodides is indicated. A complete blood count should be made and will aid in elim-

inating blood dyscrasias. A polymorphonuclear leukocytosis occurs in rapidly growing malignant sarcomas, but it is never as marked or as characteristic as that of an acute osteomyelitis

In the general physical examination the location of the tumor or tumors, whether single or multiple, certain changes in the shape of the bone, differences in feel, bone tenderness changes in the skin circulation should be noted and help in comparison in arriving at a diagnosis

General diffuse enlargement of a bone which is hard usually means chronic inflammation rather than tumor

In discussing the various types of bone tumors, I shall follow no definite classification but will try to present the types in some relationship to their source and the character of the tissue involved. Much which is interesting must, because of the scope of this paper, be omitted. All that is stated is derived from sifting the literature and from personal experience and is, in so far as is possible, an attempt at an accurate presentation of our present knowledge. Such defects as exist must be acknowledged as a personal deficiency or misconception on the part of the writer

OSTEOCHONDROMA—This represents an imbalance in the permanent bone formation in the osteogenic zones of the periosteum and the proliferation in the adjacent precartilaginous tissue

The exostoses of inflammatory origin result from an overstimulation of the center of cartilaginous cells in the attachment of the tendon (Kolliker) and resemble tumor formation so closely that they are not distinguishable histologically

Etiology—May occur from many causes

Congenital Multiple, hereditary—due to congenital variations where bony protuberances normally occur

Traumatism—Cause single exostoses, especially at the site of normal bone protuberances

Infection—Localizing in tendon attachments, produce spurs (exostoses) as in the

in motion, pressure on contiguous structures, or the formation of bursae over the growth. Fracture of osteoma may occur and be the earliest symptom

Location—Periarticular and in tendon attachments

Treatment.—Removal in cases giving symptoms, careful to reflect periosteum, excise tumor at pedicle and excise involved tendon and reattach same.

Complications.—Malignant degeneration, 7 per cent in Geschickter and Copeland cases.

Closely associated with this group are the multiple exostoses and the deforming types of chondrodysplasia.

CHONDROMAS AND CHONDROMYXOMAS.—Benign tumors occurring in small bones of hand, feet, ribs, and spine between the ages of twenty and thirty.

Central Location.—Those in small bones are usually benign and those of the sternum and vertebrae should be regarded as potentially malignant.

Etiology.—Congenital in origin and represent supernumerary joint cartilages.

Symptoms.—Swelling, especially in small bones of fingers, rarely pain after use, readily diagnosed by the x-ray.

Treatment.—Excision and cauterization, care not to transplant any of the cartilage cells.

PRIMARY CHONDROMYXOMA SARCOMA.—Young individuals under thirty; very malignant; arise in the periosteum, related to periarticular structures about the knee, shoulder, and pelvic girdle; they run a rapid clinical course with a fatal outcome. X-ray features are visible as a subperiosteal shadow which does not involve the cortex until late. Geschickter and Copeland give the cures as about 5 per cent.

SECONDARY CHONDROMYXOSARCOMA.—Usually result from malignant degeneration of benign osteochondroma, or occur as complications of Paget's disease or the hereditary types; usually involve the upper end of the humerus, ribs, or heel.

Symptoms.—There is usually a long history of pain of a rheumatic type followed by an exacerbation of this pain and in the humerus with a pathological fracture. X-ray examination may show the existence of the preceding condition with a fuzzy infiltration and destruction of the cortical bone and involvement of the medullary cavity.

Treatment.—Radical resection or amputation followed by implanting of radium or radium pack. 'Bloodgood' called these tumors myxoma and called attention to the frequency with which they recur and to the chronicity of their course. A cure

may be obtained in 20 to 25 per cent of the cases.

PERIOSTEAL OSTEOGENIC SARCOMA (Sclerosing Osteogenic Sarcoma).—These tumors occur in very young individuals (maximum age about fifteen years); they are located near the ends of the long bones, appear suddenly, grow rapidly, and show the characteristic x-ray appearance, namely, delicate radiating lines of new bone beneath the periosteum (sun ray tumor) without involvement of the periosteum.

Treatment.—Very early radical resection or amputation is the method of choice. Postoperative radiation and Coley's toxins may be of benefit. Metastasis to the lungs occur early and an x-ray of the chest is necessary at the time of examination.

Prognosis.—Poor.

CHONDROBLASTIC SARCOMA.—Arises from the young cartilage cells of the epiphyseal lines and occurs during the period of active bone formation, usually about puberty; it involves the actively growing ends of the long bones, especially the femur and tibia.

Symptoms.—Sudden onset of pain, fever, and leukocytosis, with early local tenderness over the involved bone are common symptoms and may resemble an acute bone infection. The x-ray examination while not characteristic is sufficiently so to make the diagnosis especially in the classical case. The tumor extends on both sides of the epiphyseal line, involves the shaft, and shows a periosteal shadow, that is, it shows evidences of central bone destruction with periosteal irritation.

Treatment.—Early amputation, followed by radium or deep roentgen therapy and Coley's toxins is advised.

Prognosis.—The probability of a cure is very poor.

OSTEOLYTIC SARCOMA.—So-called angiosarcoma, aneurysm of bone, malignant bone cyst; occurs at any age. It is most prevalent in the long bones, involves the central portion of the bone, is rapidly bone-destructive, and pathological fracture is common. In the younger age groups fever and leukocytosis are common. A peculiarity of the advanced tumor is the suggestion of fluctuation and pulsation. X-ray diagnosis is difficult and often it is confused with bone cysts, giant cell tumor, or Ewing's tumor, or in the younger group with osteomyelitis. The single feature of

value is the irregular destruction of the cortical bone by a central tumor, whose outlines are not clearly defined, with early periosteal reaction and an absence or very slight expansion of the cortical bone. The histological picture shows a marked degree of anaplasia in spindle cells and osteoclasts with marked vascularity. Geschickter considers that this tumor represents an early phase of osteogenesis by way of fibrous tissue and arises from the endosteum. X-ray examination of the lungs is essential as metastases occur early.

Treatment—Early amputation offers the best result but is only successful in the older patients (6 per cent five-year cures—Geschickter). Death results in the younger patients no matter what treatment is used. Following amputation, radiation and Coley's toxins may be used.

BONE CYSTS—Bone cysts occur in young individuals in the diaphysis of the long bones near the metaphysis and are most commonly found in the upper part of the femur and upper part of the humerus. They run a chronic course and the symptoms may be indefinite. Pathological fracture is frequent and, as Bloodgood has stated, is almost pathognomonic of the lesion.

Pain is not a constant finding, often it is worse after exercise. Swelling of the bones and local tenderness are present but may be entirely absent.

X-ray examination reveals the lesion and makes the diagnosis, namely, a cystic cavity in the bone of a young individual, which is sharply defined. The cortex is thinned and expanded, but there is no periosteal change.

The cyst usually contains a currant-jelly like substance, and it is lined by a fibrous lining made up of spindle cells and fibroblasts. Many variations may exist, but in none of the lesions is any bone destructive process present.

Treatment—The treatment is largely symptomatic. Pathological fractures heal and cure the condition. The present tendency is to leave the solitary cyst alone unless it is progressing.

Personally, I prefer a simple operation which removes the fibrous tissue, crushes the cyst wall, and in fact does what the fracture does, that is, heals the bone.

OSTEITIS FIBROSA—Osteitis fibrosa, osteitis fibrosa cystica, and its variants including multiple osteitis fibrosa include a

number of conditions and the name is a pathological dumping ground.

Solitary bone cysts are grouped by some writers as a variety of this lesion in young individuals. In some cases with bone destruction and giant cell formation they are considered variants of the giant cell tumor.

In the polycystic form of osteitis fibrosa the lesion is more rapid in its development than the solitary cyst, its course is relatively more rapid, the symptoms are more definite, and the process is located nearer the epiphysis.

In the x ray the lesion is more trabeculated, it seems to be made up of more than one cavity and the outline, while smooth, is not as regular as the single cyst, but is lobulated. In other variations polycystic disease of the bones occurs in such diseases as osteomalacia, in Paget's disease, and in conditions in which the parathyroid plays either the main part or at least a definite secondary one.

The histology of the polycystic group shows giant cells which are less frequent and not so large as in the giant cell tumor. There is also more fibroblastic tissue with more intercellular substance, and trabeculae of bone running through the tissue are more common than is the case with giant cell tumor.

I am not convinced that we have as yet differentiated these pathological processes. Since the essential pathological feature is one of repair, isolated forms of osteitis fibrosa may be, and I believe the following cases illustrate their relation to definite infection, typhoid fever in these cases. What the original infection produced is a question. The late result is shown by these slides.

HISTORIES William F. aged 21, was admitted to the New York Hospital with an acute appendicitis was operated upon and a gangrenous appendix was removed. During his convalescence he called attention to a swelling on his left radius which he had noticed for some months. It did not bother him except that it was larger than the bone in the other arm. Three years previous to his present illness he had typhoid fever in Roosevelt Hospital but does not remember any trouble with his arm at that time. Examination revealed a swelling over the lower third of the radius which was not tender. X ray showed a cystic cavity in the bone which was definitely outlined and which showed some evidence of production in the periosteum or thickening of the cortex around the cystic cavity. At operation a cystic cavity in the bone with material not unlike that found in a bone cyst was found. There was more detritus than is customary. It

was emptied, cauterized, the wall crushed, and the wound closed. A culture was reported as containing a pure culture of *B. typhosus*. His recovery was uninterrupted, the bone healed, and he had no recurrence up to ten years after the operation.

The next slide is one of the right shoulder in C.M., aged 25, who states that six years ago while playing basket ball he injured his right shoulder. Pain in this shoulder was intermittent in type, but disappeared under salicylates and physiotherapy. Three and one-half years ago he had had typhoid fever with an extensive phlebitis of the axillary veins. This case is reported in detail in the *Annals of Surgery*, April 1917, under the diagnosis of hemangioma cavernosum of bone. At the time of the operation, I considered it a possible result of typhoid. The cultures were negative. Dr. Elser stated in his pathological report "we are led to regard it as cavernoma in bone with organization of extravasated blood." Later Bloodgood, in a personal communication, after reviewing the case considered it a form of osteitis fibrosa cystica. A second operation two years later for an increasing difficulty in motion at the shoulder showed no evidence of a recurrence of the previous condition; however, there was a bone spur which had formed in the region of the operation and which caused restriction in motion due to mechanical causes. Just where to place this condition is questionable, but I still have the impression that it is in some way related to the extensive thrombophlebitis during his typhoid fever.

The third case is one in a man aged 51, who at the age of 38 had had a complicated typhoid fever. During the summer of 1926, after a blow received on that arm, some swelling of the radius and a prominence of the head of the ulna where noted. Gradually this deformity increased with a dull aching pain in the arm. An x-ray picture showed an irregular decalcification of the lower half of the radius with thickening of the entire shaft, an increased length of the radius with deformity of the bone, and an extensive alteration at the carpal articulation of the radius due to this overgrowth. The head of the ulna was displaced posteriorly. Dr. C. L. Gibson operated upon the arm in December, 1926, and found a cortical bone which was irregularly hard and soft with the medullary space replaced by a reddish gray material which was irregularly distributed among rather friable bone trabeculae. The pathological report was osteitis fibrosa. The culture was negative. Subsequent x-ray pictures of the skeleton and blood calcium and phosphorus examinations showed no evidence of involvement of the calcium metabolism, and none has occurred in the eight years following the discovery of the condition*.

Just where to place this condition and how to explain it is a question. I feel that it is in some way related to the typhoid fever.

In the diffuse and multiple forms the parathyroid and disturbed calcium meta-

bolism will explain their origin, especially if tumors of the parathyroid exist.

In any case of osteitis fibrosa cystica the blood calcium and blood phosphorus should be estimated. These may be normal. The calcium output as compared to the intake should then be computed and if the output is increased over the intake a systemic condition must be suspected and sought for. Local lesions in a single bone do not, in my experience, produce calcium changes of importance and the systemic calcium is not altered.

In the treatment of osteitis fibrosa, x-ray therapy is given precedence, largely, I believe, because it does no harm and relieves the bone pain. Diet is also given an important place, especially a diet rich in calcium, phosphorus, and vitamin D.

In cases with a distinct increase in the calcium output parathyroid tumors should be suspected and the parathyroids should be investigated surgically.

In the localized forms of osteitis fibrosa confined to a single bone there is a place also for radical resection of the deformed bone and, in selected cases, its replacement by a bone graft with overgrowth deformities. As yet it has not been given a sufficient trial to determine its value or lack of value.

GIANT CELL TUMOR.—This tumor occurs in adults and is situated near the epiphyseal line. It is most common at the site of active bone growth, *i.e.*, at the lower end of the femur, upper end of the tibia, and the lower end of the radius.

Trauma is a more definite entity in the history of this tumor. Barrie³ considered it a type of osteomyelitis and gave it the name of "hemorrhagic osteomyelitis," with infection as a possible cause, and with the resultant changes in the bone producing the tumor after the infection had disappeared. The important factor is to omit the name sarcoma in relation to the nomenclature of this tumor.

Symptoms.—Pain is a more or less constant factor and usually follows some trauma, which is important in the patient's mind. The pain is not acute but is a gnawing aching pain and made worse by use of the extremity. Swelling is noted early, the ache and pain being associated with the swelling.

In a patient in the third decade with a tumor in the customary region, which involves the bone which is hard in character,

* The author is indebted to Doctor Gibson for the report of this case.

the x-ray will readily make the diagnosis. It will show a circumscribed lesion with evidences of cortical bone destruction at or near the epiphyseal line without periosteal reaction and with definite expansion of the bone. The shadow is irregularly hazy, the cortex is rapidly thinned out, and perforation of the cortex is frequent. The joint cartilage is seldom perforated and joint involvement is rare.

Pathological Appearance.—The tumor mass is quite vascular and bleeds readily, it is of a reddish brown or grayish brown color and is quite friable and may have definite fibrous tissue strands in or about it. On the shaft side the bone is firmer and harder than the normal bone. The bone over the tumor varies in thickness.

Microscopic Appearance.—The tissue consists of a mass of multinucleated giant cells in a varying mass of smaller round or irregular shaped spindle cells. Giant cells are more numerous about areas of hemorrhage or bone spicules.

Complications.—Recurrences occur if the tumor tissue is incompletely removed. Local recurrences are relatively more cellular than the original but preserve the typical appearance. Reports of tumors of the typical giant cell type which have metastasized appear in the literature, and the nature of the original tumor is a debatable one. The metastases from these tumors, however, are osteogenic sarcoma and do not show the typical giant cell structure.

Treatment.—Conservative treatment is indicated and amputation is, at the present time, never indicated. Curettement with cauterization as recommended by Bloodgood has given good results in the properly selected cases. Recurrences have been more frequent when this has been incomplete or has not been followed by cauterization. When the cavity is unusually large or the soft parts cannot be properly allowed to fall into the cavity, a muscle flap to fill the bone defect will hasten the repair process. Wide open drainage, especially with gauze packing, is not advisable as infection is prone to occur and leaves a long-standing drainage wound, often necessitating secondary operation to close the wound. When packing is required, I prefer the vaselin gauze pack as recommended by Orr in the treatment of osteomyelitis, and leave it alone until it is practically forced out of the wound by the growing tissue behind it.

Radical resection of the bone may be used in selected cases, especially in the radius, fibula, and ulna and the removed bone replaced by a suitable bone graft. In my hands 5 cases—3 radius, one ulna and one fibula, have given 4 excellent results, with one partial failure in a case of the radius due to the fracture of the graft produced by a too earnest examination elsewhere, to see if the graft was solid. There were no prolonged disabilities except in the last-mentioned case.

Röntgen and Radium Therapy.—Early cases and more advanced cases have been treated throughout by this form of therapy with successful results. Under treatment the bone tumor apparently increases in size until the cortex ruptures and then retrogresses and heals. The implantation of radium as a part treatment in curettement is not advisable because of the delay in healing produced by the action of the radium. The selection of the type of treatment to be used must be left to the surgeon. In any case where doubt exists preliminary radiation can be used until consultation determines the best procedure for the given case. Ill-advised operations or amputations are not necessary at the present time and nothing is gained by a lasty operation.

EWING'S SARCOMA.—Ewing⁴ described a tumor of bone which occurred in young individuals usually under 25, which probably arises from the endothelium.

Etiology.—The etiology is uncertain. Trauma is indefinite but is usually given as the beginning of the trouble; however, careful analysis of my cases shows that either the lesion was present before the trauma or was so remote that its relation to the onset of the tumor is open to very justifiable skepticism.

Symptoms.—Pain is a constant finding. It varies extremely in character but is usually dull aching "rheumatic" in character, sometimes with shooting pains located over a long bone. It is increased by use, and rest does not cause it to disappear completely. At first the pain may be intermittent, but later it becomes constant with variations in degree. Pain at night is among the constant features and often it is stated to be more severe then. Swelling or tumor may be the first symptom, but usually it is preceded by pain. The swelling is variable in size, usually diffuse in relation to the contour of the

bone, and associated with deep tenderness over the swelling. Occasionally the overlying tissues may be edematous. Later, changes occur with local heat and increased size of the skin veins. Change in the size and extent of the tumor also may occur with evident regression of the tumor.

Pathological fracture is relatively rare but does occur; in one of my cases it was an early symptom.

An increase in the body temperature is common.

Blood examination is variable but an early leukocytosis, especially in cases with fever, is common, with an occasional increase in the eosinophiles. The hemoglobin and red cells may show the picture of a slight secondary anemia.

Urine Examination.—Cases with temperature may show a trace of albumin in the urine and other indications of kidney irritation. Bence Jones bodies are not found.

Complications.—Metastases occur late and are usually diffuse. They involve the lungs, other bones than those involved, especially the skull and vertebrae. With the involvement of these structures, neurologic complications and motor disturbances occur.

Diagnosis.—In a young individual about twenty with indefinite bone pain and the symptoms above described the x-ray is essential for diagnosis. The tumor is usually located in the diaphysis of a long bone, rarely involves the epiphysis, shows a hazy, shaggy shadow with the so-called "onion peel" reaction of the periosteum with thickening of the bone. There is an increased density of the bone, especially in the medullary portions, and the tumor seemingly extends in the long axis of the bone.

In the early stages bone production is more common. Later, bone destruction occurs and the rapidity of this process determines the appearance of a pathological fracture.

Differential Diagnosis.—Inflammatory diseases of the bone, pyogenic, tuberculous, and syphilitic, must be distinguished, but a careful study should separate these especially if the various clinical tests are made. As Bloodgood has stated, a therapeutic test in doubtful cases in which syphilis is suspected is valuable.

Multiple myeloma and osteogenic sarcoma may be confused with Ewing's tumor.

In multiple myeloma the lesion is multiple, or, if single, the periosteal reaction is not as marked and early pathological fracture is common. The x-ray examination of the skull will help as it is not involved in early cases of Ewing's tumor. Bence Jones bodies are also frequent in the urine.

Osteogenic sarcoma is located at the end of the bone near the diaphyseal line. Ewing's tumor is in the shaft and rarely extends to this region. Osteogenic tumor is more destructive in appearance and the laminated periosteal bone is rarely seen.

Metastatic tumors produce more bone destruction and if suspected from the x-ray appearance, and since they occur in later life, usually show the site of the original tumor on careful x-ray aid clinical investigation, and lead to the proper diagnosis. Hypernephroma will give characteristic urinary findings, especially if sought for, and a palpable kidney will be suggestive.

Pathology.—The microscopic appearance of Ewing's tumor is characteristic. The constant cell is a small more or less polyhedral cell with a round or oval deeply staining nucleus. The cell cytoplasm is scanty and does not stain. Mitotic figures are common. Where these cells are involving the bone, various stages of bone reaction, fibroblasts, osteoblasts, and osteoclasts may be seen, with bone formation and bone destruction progressing in varying areas.

Treatment.—Radiation of the tumor is the method of choice and may produce a cure in selected cases. When the tumor retrogresses or is held stationary, surgery is indicated, but sufficient time is usually given to consult as to the best surgical procedure for the given case.

Radical resection of the involved bone with the contiguous muscle attachments is the method of choice surgically, in my opinion, and should be done when retrogression is established, that is, it should always be preceded by proper satisfactory radiation. The removed bone should be replaced by a suitable bone graft and muscle attachments reattached to the grafted bone. Personally, I feel that this method has not been given a sufficiently thorough trial to determine its efficacy, and I believe it can be resorted to earlier and more frequently when its nondisabling features are compared to that of amputation

Amputation.—Amputation should not be resorted to without preliminary radiation. Just where amputation belongs in the treatment of this condition, is open to speculation. Radiation after amputation is always advised.

Prognosis.—The prognosis is better in the cases of long duration, in the cases which respond to radiation promptly and in the cases in which the local lesion is excised promptly.

Preliminary operative investigation for biopsy is not indicated, although Geschickter and Copeland think it does not necessarily affect the prognosis.

MULTIPLE MYELOMA.—This is a disease of adult life and occurs after forty in the vast majority of cases; it is more common in men (about $2\frac{1}{2}$ to 1). Little is known about its cause, but possible hereditary tendencies may exist.

Symptoms.—Pain is indefinite in character, so-called rheumatic or neuritic type. It is aggravated by use and by pressure, and frequently its recognition is brought about by some unusual physical effort followed by an exacerbation of the pain. It is intermittent in character and may completely disappear. Later it becomes constant and more intense, especially in the involved area. With vertebral involvement, cord lesions, peripheral paralysis, or paraplegias occur.

Tumor.—Swelling over a given bone may be the earliest symptom. Later these become multiple and give symptoms depending on their location, such as changes in shape of the spine, interference with mastication, etc.

Fracture.—Pathological fracture is frequent and may be the earliest symptom; it is frequent in the ribs and short bones. Multiplicity of the fractures is also a characteristic phenomenon.

Lung involvement, bronchitis, emphysema, and pleurisy are common, the latter when the ribs are involved.

In vertebral disease, compression of the cord or pressure on the nerves will give various types of paraplegia.

Kidneys.—Various forms of kidney disturbances are reported. Bence Jones bodies are present in 60 to 70 per cent of the cases and are significant, if not a diagnostic finding.

Gastric disturbances are not infrequent and vomiting may be annoying, especially in cases with cord involvement.

The blood picture is not characteristic. In the differential white count an increase in eosinophiles has been noted. Myelocytes are also reported and abnormal mononuclear types may be found (Turk's irritation phenomenon).

Diagnosis.—An x-ray examination of the skeleton is helpful in diagnosis and will show the multiple lesions in the bones. The lesion is central in location, is bone-destructive, and rarifies the bone early. Confluence of contiguous areas is frequent. The tumor cell is of the plasma cell type.

Treatment.—The treatment is essentially palliative and symptomatic. Radiation will cause local areas to disappear, but they recur either locally or elsewhere; eventually they become resistant to radiation.

Fractures and other complicating conditions are treated by appropriate measures.

Prognosis.—The prognosis is hopeless and no cases are cured.

METASTATIC TUMORS.—Various forms of carcinoma (breast, prostate, etc.) metastasize to bone. They may occur early or late and are bone-destructive in character producing early pathological fracture. They may be single or multiple and the symptoms are variable with pain and dysfunction, loss of weight, anemia, early cord symptoms in vertebral involvement, etc. Deep and intense x-ray therapy helps the pain and in isolated cases temporarily arrests the disease. The prognosis is hopeless.

Another rarer type of carcinoma of the bone may occur, namely, that associated with a chronic draining sinus. The following case of epithelioma of the bone, which occurred in the tibia in a sinus of an old osteomyelitis, illustrates this type.

Man, aged 65, had osteomyelitis of the tibia as a child. This was opened and has been discharging for about sixty years. This discharge up to nine months ago was slight and from time to time contained bits of bone which were extruded. About nine months before he was seen by the author there was an increase in the discharge which has gradually become more profuse and bad smelling, and recently there has been a tendency for the ulcer (sinus) to bleed. There was a typical epitheliomatous ulcer involving the skin about the sinus which extended into the bone and which in the x-ray showed extensive involvement of the medullary bone. The inguinal nodes were palpable but did not seem larger than the uninvolved side. The chest x-ray was negative. Mid-thigh amputation was done. Six months after the amputation enlargement of the inguinal nodes occurred and at nine months definite lung involvement took place and death occurred about two months later.

ARSTACT OF DISCUSSION

DR. PHILIP L. FORSTER, Albany: I think a word or two regarding the use of Coley's toxin may not be amiss. It is my impression that it is either not used at all because some men feel opposed to it, though without any definite reasons for their opposition, or else it is used more or less indiscriminately, without proper regard for the type of tumor under treatment. It should be understood that Coley's toxin, which is a mixture of the toxins and derivatives from killed cultures of *Streptococcus erysipelatis* and *Bacillus prodigiosus*, is not held forth as a cure in itself. It is used in conjunction with other measures such as irradiation and operation. Its greatest value, according to Dr. Coley, is its use when combined

with thorough irradiation in cases of endothelial myeloma, or Ewing's sarcoma. Also, in cases of osteogenic sarcoma and, to a lesser degree, in multiple myeloma. It is my feeling that Coley's toxin should be used more extensively, always bearing in mind that it is not a curative measure, but merely an aid. Cases recorded indicate, generally, better results with the use of the toxin—and certainly there is nothing to lose by its use.

126 EAST 37TH STREET

ARE HOSPITALS TOO HUMANITARIAN?

A successful business man was discussing hospital problems with Dr. Frank J. Walter, Superintendent of St. Luke's Hospital in Denver, and retiring President of the Colorado Hospital Association. He told Dr. Walter that hospital executives stress the humanitarian principle too strongly, and said the hospitals would be much better off if run on the cold maxims of business. What Dr. Walter thinks of that idea he told in an address before the Association.

All recognized ethical hospitals, he remarked, are for the most part alike in equipment and facilities for the care of their cases and in the type of nursing service given to the patients. What is it, then, which makes certain hospitals the most outstanding in the minds of the public? It is the spirit of humanity which is more fully practiced in these hospitals than in the others. These hospitals are the ones which anticipate their communities' needs and present ways of meeting them. These hospitals are able to keep themselves free from political interference both within and without. These hospitals are continually striving to make their communities health-conscious. These hospitals even in this time of business stress and uncertainty are not sacrificing their scientific programs in promoting their economic interests.

Without the spirit of humanity each hospital of the community, or of the nation, would be an independent, self-centered, uncooperative unit; the scientific advancement for the care of the sick would be practically at a standstill. There has developed, in the code of ethics among the professions caring for the sick, an unwritten principle that any discovery which will either aid in therapeutic treatment, or will expedite the administering of such treatment to patients, shall not be withheld or commercialized by the discoverer, but shall be freely given to the medical group so that all may benefit thereby. Without the spirit of human kindness there would not be this willingness of one individual or institution to share this knowledge and experience for the good of the whole. Without it, the common law of courtesy, demanding that one hospital superintendent reciprocate in extending support and kindness to other hospital executives who have performed similar services and courtesies for him, would not be exercised.

The entire system of voluntary hospitalization is built upon the spirit of humanity. Without it this system would collapse. State Medicine would then be a reality, since the private hospital is the only bulwark against it.

EIGHT-HOUR DAY FOR NURSES

The rapidity with which hospitals are adopting the eight-hour day for special-duty nurses is indicative of the satisfaction this innovation is giving. In greater New York alone, eleven of the larger hospitals have introduced this reform and the *New York Medical Week* reports that it is giving general satisfaction to patients, doctors, and nurses.

The twelve-hour shift is incompatible with the modern trend to a shorter working day. Naturally the latter leaves the nurse fresher and more alert; and the patient's response to this is quick and favorable. Far from resenting the appearance of a third on the scene, most patients appear to welcome change as a break in the inevitable monotony of hospitalization.

Judiciously handled, the eight-hour day need involve no added expense to the patient or the hospital. The fee of the individual nurse is naturally less and the food allowance is reduced: eight-hour workers are not paid for three meals each. The patient is therefore assured of better nursing service at no greater cost and employment is created for a large number of nurses who have suffered greatly from the enforced idleness of the past few years.

The attitude of physicians toward this innovation reflects the favorable response of patients, and nurses. As long as standards of service are not lowered, the medical profession is glad to cooperate in securing better working conditions for one of its most valued aides.

Symposium on Gonorrhea

ON THE TREATMENT OF ACUTE GONORRHEAL URETHRITIS IN THE MALE

ALBERT M. CRANCE, M.D., F.A.C.S.
Geneta

In the words of Pelouze "It is probable that nothing would do more toward the ultimate solution of the treatment of gonorrhea than for us universally to realize that our antiseptics and bactericides do good only in so far as they are able to encourage tissue reaction, and that any direct bactericidal action they may have is incidental and of secondary importance. The result of this attitude would be to stimulate investigation in other directions that offer more chance of real success, and to stop the wild scramble for the ideal chemical germicide that probably is not to be." This same author further states that "the use of certain substances in the urethra is so depleting to the mucous membrane that it not only retards cure but prevents it." This illustrates very well the very basic principle of this paper.

We must all realize that gonorrhea in the male still continues to remain without any definitely specific treatment. There is, however, a specific management of the disease which does result in its satisfactory termination, only, however, when the confidence of the patient and his cooperation are obtained at the very outset of the treatment.

The first important step in any given case is to make positive the diagnosis by smear. This is mentioned only because one is surprised with the frequency with which physicians neglect this procedure. Each year the writer sees several cases which have been placed under treatment for gonorrheal urethritis, but which were not gonorrheal urethritis at all. In fact, the examination consisted of a brief history and the writing of prescriptions, without even inspecting the origin involved. Physicians who treat gonorrhea in this light are just those who profess to say they do not treat it at all, and yet by so doing they are delaying this patient's recovery.

The second important point is to treat the urethritis for the first week or two by internal treatment alone. This should con-

sist of a good salol and santalwood compound capsule (10 minims), taking one or two after meals and two again at bedtime. A diet free from condiments is advisable. Water should not be forced because it produces more frequent micturition and, consequently, invites complications in the posterior urethra.

Third, it is important also to attempt to establish an early temporary immunity by the use of very minute doses of vaccine. In spite of the general objection to the use of gonococcus vaccine, I believe that when this is properly used in minute doses, at least twice a week, sufficient evidence exists to conclude that it does shorten the duration of the infection. The writer has been fortunate enough to have used intradermal injections of a gonococcus bouillon filtrate, such as reported by Corbus of Chicago, in over 100 cases. In a few cases very prompt results were noted, but in the vast majority the duration of the attack lasted about the same as with vaccine. Nevertheless, I should miss the use of some such "booster" treatment in my own practice.

Recently, a new antigen, under the name of Neiso-Lysate has come to our attention. The writer has used it only for a few weeks, but already some very promising results have been noted. Certain workers at the University of Illinois have used it in 174 male patients, and in less than 5 per cent of these no local treatment whatsoever was used. The low incidence of complications in this series was impressive. Doses of 3 minims are given subcutaneously twice a week, increasing the dosage very gradually.

Unquestionably, most of us have often wondered just what is accomplished by local treatment, whether it is a stimulation of the mucous membrane or whether the solution used actually does destroy surface organisms. It is certain that no solution can be expected to reach all of the invading gonococci. Consequently, it seems

that the day is not far off when local treatment, such as the use of 0.25 to 0.5 per cent protargol, 10 to 15 per cent argyrol, and other silver derivatives, will be considered a detriment rather than an asset. Any of these should be used with great precaution, only after the acute symptoms have subsided and when it is not easy to find gonococci in the smear.

After the second week, however, when the acuteness will have somewhat subsided, there are some cases in whom injections can be used to advantage in shortening the duration of the disease. Before advising such treatment, however, proper office instructions as to the care as well as to the proper technic necessary for injections must be emphasized. No patient should ever leave the office with merely verbal instructions as to this technic. Any physician who is not willing to take the time to demonstrate the use of a bulb syringe for urethral treatment, should never prescribe it. More harm can be done by this one element than many of us realize. Such injections should not be used more than twice a day and if each injection is retained less than eight minutes, both syringe and solution might better be discarded in the proverbial ash can.

In those cases requiring office irrigation the writer believes that it will best be accomplished by the use of a bulb syringe and some mild astringent solution, such as neutral acriflavine, potassium permanganate, or their equivalent. Before leaving the subject of local treatment, may I say that we are passing through this era at the present time. One must realize that a great many cases are prolonged by over-treatment rather than by insufficient treatment. Even the use of sounds, which is so commonly carried out in the presence of a purulent discharge, I consider one of the worst procedures in the practice of medicine. Why anyone could believe that dilating an already inflamed and infected mucous membrane could possibly help is hardly conceivable. The use of sounds is used in chronic cases with crypts or folds of mucous membrane, foci of infection. Necessary in strictures, if properly handled, at least as an acute measure, but they are due to the urethra than to the

THE GLASS TEST

The two-glass test is a very valuable procedure in checking up the progress of the disease, and, for this reason, patients with this infection must be urged to appear at the office twice weekly prepared to void. There have been many interpretations described in textbooks regarding the two-glass test. This does not need to be repeated herein. The presence of shreds, even in the first glass, long after discharge has ceased, is a definite indication to continue treatment, because, with shreds present, the patient is still infected with gonorrhea. Occasionally, both glasses will show cloudiness and not infrequently is this due to phosphates which, of course, will easily be differentiated by the addition of a few drops of acetic acid. Another important interpretation of the two-glass test is the fact that if the shreds are present in both glasses, injections should never be used. In these cases we are undoubtedly dealing with a posterior involvement which will require very gentle prostatic massage with a full bladder, approximately once a week.

Since the use of antigen treatment, either intradermally or subcutaneously, combined with the use of internal urinary sedatives, the writer has definitely noticed more rapid recovery, generally speaking, and certainly a very noticeable decrease in the percentage of complications. The occasion has been very rare indeed when it has been necessary to fulgurate or otherwise treat certain glands in the roof or floor of the urethra. Such technicalities are splendid subjects to talk about but hardly adaptable as a cure for gonorrhea. The writer feels quite the same regarding diathermy. After persistent trial, he is through with it in acute urethritis or any of its complications.

COMPLICATIONS

Complications are frequently caused by too much local treatment and yet many cases are seen by every urologist only at the time of complications in which no local treatment has been used. The writer believes very firmly that a certain number of complications are due simply to variations in the virulence of certain gonococci. Some strains of the organism tend to spread and produce complications very early in the disease, whereas, on the other hand, milder strains account for the rapid recoveries in the first week or two, which

we occasionally see. A few years ago 8 patients who had all been infected from the same source were under the care of the writer. Six of the 8 developed prostatic abscess during the first two or three weeks and another one a very severe epididymitis. Does this not suggest that the virulence of the organism is a factor in many who develop complications?

PREVENTION—The prevention of complications should be a part of the treatment in every case. Occupation, exercise, habits, and other things are all contributing factors. For example, it has been noted that epididymitis frequently occurs in paper hangers. Such occupations requiring reaching and twisting of the body cannot help but induce organisms into the vas deferens, and likewise to the adjacent structures. Rest is the best preventive of complications, and our nearest approach to this is a sincere effort on the part of the patient to consider this factor at all times during his infection.

Sounds, bougies, too early massage of the prostate, improper drainage, and chemical irritation are, of course, well known causes of complications, such as epididymitis, prostatic abscess or edema, vesiculitis, peri urethral abscess, and stricture. Peri urethral abscess is certainly much less in its occurrence when the gonorrheal bag is omitted—all of these commercial attachments are designed to shut off the urethra, where the penis is suspended in the gauze hammock. For this reason, I merely mention that the use of a square gauze, 8 by 10 inches, pinned to the underwear and worn as an apron, allows proper drainage, freedom from pressure, and curiously lowers the incidence of complications.

TREATMENT—In a paper such as this, one cannot include in detail the treatment of all of the various complications such as have just been mentioned. Epididymitis, probably the most common one, is still without a specific remedy. Calcium, in the form of gluconate or diasporal, given intravenously, together with rest in bed, elevation and immobilization of scrotum and the application of heat, is probably the best treatment for this phase of the infection. It relieves the pain immediately and the swelling and disability in from four to seven days. After a thorough and persistent effort with diathermy, the writer's opinion is that just as many cases were made worse as were made better.

Acute prostatic abscess, prostatitis, and vesiculitis are best handled by hospitalization, where twice a day warm rectal irrigations may be used to advantage combining this with the daily intravenous use of calcium. Peri urethral abscess naturally requires surgical drainage. During the past two years, since using bouillon filtrate or antigen treatment as a part of the routine, there has definitely been a lower incidence of complications during treatment. This part of the treatment is continued weekly or twice weekly in any complication which might arise, along with the above mentioned pseudo specifics.

DETERMINATION OF CURE

The average patient will soon cease to make his appearance at the office after the discharge disappears unless he is constantly warned regarding the importance of a cure. The author has actually found it very beneficial to get the patient clinically interested in watching the examination at each visit, especially of the two glass test. If it is pointed out to him that these will soon disappear with a little further treatment, he is certainly going to be more inclined to adhere to the routine until his case shows complete recovery. In the uncomplicated case, after the discharge has been absent for three weeks and both glasses are free from shreds, he is then placed on a probationary period and appears at the office once weekly, simply for observation without any further treatment. At this time, and not until this time, is he discharged as recovered if conditions continue to remain clear. Too many false cures are determined simply because gonococci are not found in the smear. Recurrences or relapses in gonorrheal urethritis in most instances, are due to improper follow-up. Persistent morning discharge is frequently due to the morning squeezing habit. This continually irritates the anterior urethral glands. It is one habit which from the very beginning *must be eliminated*.

In conclusion therefore, the author urges that conservatism must be constantly kept in mind when treating acute gonorrhea. Internal treatment along with the administration of antigen, or very minute doses of vaccine have proven more efficient than any form of irrigation or injection in the first week or two, or even three weeks after the onset. If injections are to be used, they should never be started

until this time. Cooperation as well as confidence must be gained from the very beginning, then subsequent follow-up and cure of the disease will result. It should always be remembered that it is the resistance of the patient's own urethra that destroys the gonococcus and not what we

put into it. Our duty is to increase the ability of the urethra to rid itself of the infection, and the sooner we realize that this cannot be accomplished by any chemical action alone, the sooner will we be headed in the right direction in the management of this infection.

THE TREATMENT OF CHRONIC GONORRHEA IN THE MALE

ERNEST M. WATSON, M.D.

From the Department of Urology, Medical School, University of Buffalo, and the Urological Service of the Buffalo City Hospital

It is seldom that male patients in the early and middle decades of life become any more dejected during protracted treatment or grasp any more hopefully to well-directed encouragement than when their own intuition, their friends, or perhaps a questionably outspoken physician labels their case one of chronic gonorrhea.

How often have we had to answer such questions as, "Is this disease really curable, doctor?" "If I am cured of the discharge will the poison still be in my system?" "Will this come back on me in later life?"

These few words of introduction serve only too well to marshal before our memory a very appreciable array of patients, whose gonorrheal infection had become chronic. A condition sometimes due to markedly virulent organisms in a particularly susceptible field, at other times to inadequate or ill advised treatment, at others to irritative and somewhat heroic measures too long continued, and finally to unrecognized extension of the infection beyond the urethra itself.

The multiplicity of the drugs suggested for internal medication, the pages that have been compiled advising when to irrigate the urethra, in preference to treatment by injections, and likewise the same number of pages by equally competent observers cautioning against the therapeutics of irrigations because urethral injections should be the method of choice, make us all appreciate that the last chapter has yet to be written in the management of gonorrheal infection.

The treatment of gonorrhea is an art. It always has been, and may continue to be for many decades to come. This art can rise to a high level of expression only when its underlying basis is a well-ingrained knowledge of the anatomy of the

lower urinary and genital tracts, of the pathological changes in these structures secondary to infection, and the effects on the normal and changed tissues of the various chemical agents employed to combat the infection. The more gently, the more regularly, the more thoroughly we treat our early cases of urethral infection the less chronic gonorrhea are we going to be called upon to treat.

Of basic importance in handling our cases of chronic gonorrhea is the accurate use of the microscope and the faithful observance of the two- or three-glass test.

When the discharge persists, even intermittently, with the offending organisms still present in the stained smears, for longer than 3 to 4 weeks we may readily assume that we are dealing with a resistant infection that for a workable basis we can term chronic. The appearance of a discharge at the meatus means that the anterior urethra is involved. This may be involved chronically from a deep invasion of a few organisms in the submucosa, or may be involved because one or more of the urethral glands have become infected. Often we can gently palpate along the urethra and locate a small shot-like structure which may or may not be tender, and immediately our suspicions are well founded that we have a localized focus which very probably is playing an important part in keeping infected the anterior urethra. When the anterior urethra alone is infected or the anterior urethra plus Cowper's glands or other periurethral glands, the second and third glass of voided urine is clear and without shreds. The first glass of urine passed in this instance contains the incriminating evidence of cloudiness and shreds. In chronic gonorrhea with a slight or moderate discharge containing the gono-

cocci and with the second and third glass of urine clear, we are justified in continuing our treatment of the anterior urethra for a week or two, or even three, by such means as we feel best suited to eradicate the infection. A method that is yet to be replaced in its simplicity and effectiveness is to use about three pints of a warm solution of potassium permanganate in a strength of 1:5000 to 1:8000 as an anterior urethral irrigation. The fluid is allowed to flow gently into the urethra, leaving plenty of space for the return flow by not holding the irrigating nozzle too tightly against the meatus and regulating the force of the flow by well-timed pressure of the thumb and finger on the rubber tubing back of the nozzle. In anterior urethral involvement alone nothing is to be gained by allowing the fluid to run back into the bladder, and often extension of the infection to the posterior urethra and adnexa is brought about by this procedure. In mentioning warm permanganate as irrigating fluid in chronic anterior urethritis of gonorrheal origin, the author is not unmindful of the many other chemicals that may be used. Acriflavin 1:30,000, mercurochrome 1:8000 to 10,000, silver nitrate 1:15,000, bichloride 1:60,000, have all been used in varying strengths. The author believes, however, that for the needs at hand they are not superior to permanganate. In augmenting the therapeutics of permanganate irrigations the urethral injections of a 5 to 10 per cent fresh solution of a silver nuclein has been very effective. A plan of proven value has been to give a urethral irrigation of permanganate two or three times a week followed immediately by a urethral injection of 4 c.c. of a 10 per cent solution of argyrol which is held in the urethra for five minutes. Great care should be taken not to overdistend the urethra and to use all possible gentleness. After suitable instructions the patient is then given a prescription of argente 1:60, 4 c.c. of which he uses three times a day, after voiding, as a urethral injection, with instructions to hold the solution in the urethra for five minutes.

In by far the most instances the chronic infection of the anterior urethra is kept up by an active, subacute, or not rarely by a latent focus in the posterior urethra, the verumontanum, the prostate gland, the seminal vesicles, ampullae, and in some instances even the epididymis after the lat-

ter has once become infected. Infection in any of the structures just mentioned which lie back of the external sphincter or cut-off muscle at the onset and usually for some time afterward give a definite cloudiness in the first and second and also the third glass of voided urine—which cloudiness when we examine the sediment from the glasses microscopically, we find to be due to pus, also almost without exception—while the subjective symptoms are present, showing gonococci in the stained smears.

Our determination of the structure or structures involved when the two or three glasses of voided urine are cloudy is first a matter of rectal palpation. On gentle rectal examination of the chronic case if the prostate gland is changed in consistency, if the gland is enlarged, somewhat indurated, not freely movable, we are justified in massaging it carefully and expressing a few drops of prostatic fluid for examination. A thick yellow drop of prostatic fluid is suggestive of infection, and when under the microscope this fluid contains 10 to 20 to 100 per cent of pus cells, we are dealing with an infective prostatitis.

For this condition a course of gentle, later increasing to firm prostatic massage every three to four days is indicated. If on rectal examination the seminal vesicles are enlarged, swollen, and tender, a frequently associated condition with prostatitis, they, too, should be gently stripped of their contents. Occasionally the vesicles are much more strikingly involved than the prostate which remains rather small, soft, and freely movable; in that case the rectal massage is confined particularly to the vesicular stripping. Following rectal massage urethral irrigations—at first to the anterior urethra—should be continued, together with the injections. This is done to limit any more extensive involvement of the urethra, and to gradually overcome that which always exists there. As the urethral discharge practically disappears and the second and third glasses of voided urine remain cloudy, 4 to 5 c.c. of 10 to 15 per cent argyrol deposited in the posterior urethra by means of the Keys-Ultzman syringe and the excess allowed to flow beyond the internal sphincter into the bladder over the trigone is very helpful. At this time, too, deep urethral irrigations into the bladder allowing the patient to void the

until this time. Cooperation as well as confidence must be gained from the very beginning, then subsequent follow-up and cure of the disease will result. It should always be remembered that it is the resistance of the patient's own urethra that destroys the gonococcus and not what we

put into it. Our duty is to increase the ability of the urethra to rid itself of the infection, and the sooner we realize that this cannot be accomplished by any chemical action alone, the sooner will we be headed in the right direction in the management of this infection.

THE TREATMENT OF CHRONIC GONORRHEA IN THE MALE

ERNEST M. WATSON, M.D.

From the Department of Urology, Medical School, University of Buffalo, and the Urological Service of the Buffalo City Hospital

It is seldom that male patients in the early and middle decades of life become any more dejected during protracted treatment or grasp any more hopefully to well-directed encouragement than when their own intuition, their friends, or perhaps a questionably outspoken physician labels their case one of chronic gonorrhea.

How often have we had to answer such questions as, "Is this disease really curable, doctor?" "If I am cured of the discharge will the poison still be in my system?" "Will this come back on me in later life?"

These few words of introduction serve only too well to marshal before our memory a very appreciable array of patients, whose gonorrheal infection had become chronic. A condition sometimes due to markedly virulent organisms in a particularly susceptible field, at other times to inadequate or ill advised treatment, at others to irritative and somewhat heroic measures too long continued, and finally to unrecognized extension of the infection beyond the urethra itself.

The multiplicity of the drugs suggested for internal medication, the pages that have been compiled advising when to irrigate the urethra, in preference to treatment by injections, and likewise the same number of pages by equally competent observers cautioning against the therapeutics of irrigations because urethral injections should be the method of choice, make us all appreciate that the last chapter has yet to be written in the management of gonorrheal infection.

The treatment of gonorrhea is an art. It always has been, and may continue to be for many decades to come. This art can rise to a high level of expression only when its underlying basis is a well-ingrained knowledge of the anatomy of the

lower urinary and genital tracts, of the pathological changes in these structures secondary to infection, and the effects on the normal and changed tissues of the various chemical agents employed to combat the infection. The more gently, the more regularly, the more thoroughly we treat our early cases of urethral infection the less chronic gonorrhea are we going to be called upon to treat.

Of basic importance in handling our cases of chronic gonorrhea is the accurate use of the microscope and the faithful observance of the two- or three-glass test.

When the discharge persists, even intermittently, with the offending organisms still present in the stained smears, for longer than 3 to 4 weeks we may readily assume that we are dealing with a resistant infection that for a workable basis we can term chronic. The appearance of a discharge at the meatus means that the anterior urethra is involved. This may be involved chronically from a deep invasion of a few organisms in the submucosa, or may be involved because one or more of the urethral glands have become infected. Often we can gently palpate along the urethra and locate a small shot-like structure which may or may not be tender, and immediately our suspicions are well founded that we have a localized focus which very probably is playing an important part in keeping infected the anterior urethra. When the anterior urethra alone is infected or the anterior urethra plus Cowper's glands or other periurethral glands, the second and third glass of voided urine is clear and without shreds. The first glass of urine passed in this instance contains the incriminating evidence of cloudiness and shreds. In chronic gonorrhea with a slight or moderate discharge containing the gono-

cocci and with the second and third glass of urine clear, we are justified in continuing our treatment of the anterior urethra for a week or two, or even three, by such means as we feel best suited to eradicate the infection. A method that is yet to be replaced in its simplicity and effectiveness is to use about three pints of a warm solution of potassium permanganate in a strength of 1:5000 to 1:8000 as an anterior urethral irrigation. The fluid is allowed to flow gently into the urethra, leaving plenty of space for the return flow by not holding the irrigating nozzle too tightly against the meatus and regulating the force of the flow by well-timed pressure of the thumb and finger on the rubber tubing back of the nozzle. In anterior urethral involvement alone nothing is to be gained by allowing the fluid to run back into the bladder, and often extension of the infection to the posterior urethra and adnexa is brought about by this procedure. In mentioning warm permanganate as irrigating fluid in chronic anterior urethritis of gonorrheal origin, the author is not unmindful of the many other chemicals that may be used. Acriflavin 1:30,000, mercurochrome 1:8000 to 10,000, silver nitrate 1:15,000, bichloride 1:60,000, have all been used in varying strengths. The author believes, however, that for the needs at hand they are not superior to permanganate. In augmenting the therapeutics of permanganate irrigations the urethral injections of a 5 to 10 per cent fresh solution of a silver nuclein has been very effective. A plan of proven value has been to give a urethral irrigation of permanganate two or three times a week followed immediately by a urethral injection of 4 c.c. of a 10 per cent solution of argyrol which is held in the urethra for five minutes. After suitable instructions the patient is then given a prescription of argenticide 1:60, 4 c.c. of which he uses three times a day, after voiding, as a urethral injection, with instructions to hold the solution in the urethra for five minutes.

In by far the most instances the chronic infection of the anterior urethra is kept up by an active, subacute, or not rarely by a latent focus in the posterior urethra, the verumontanum, the prostate gland, the seminal vesicles, ampullae, and in some instances even the epididymis after the lat-

ter has once become infected. Infection in any of the structures just mentioned which lie back of the external sphincter or cut-off muscle at the onset and usually for some time afterward give a definite cloudiness in the first and second and also the third glass of voided urine—which cloudiness when we examine the sediment from the glasses microscopically, we find to be due to pus, also almost without exception—while the subjective symptoms are present, showing gonococci in the stained smears.

Our determination of the structure or structures involved when the two or three glasses of voided urine are cloudy is first a matter of rectal palpation. On gentle rectal examination of the chronic case if the prostate gland is changed in consistency, if the gland is enlarged, somewhat indurated, not freely movable, we are justified in massaging it carefully and expressing a few drops of prostatic fluid for examination. A thick yellow drop of prostatic fluid is suggestive of infection, and when under the microscope this fluid contains 10 to 20 to 100 per cent of pus cells, we are dealing with an infective prostatitis.

For this condition a course of gentle, later increasing to firm prostatic massage every three to four days is indicated. If on rectal examination the seminal vesicles are enlarged, swollen, and tender, a frequently associated condition with prostatitis, they, too, should be gently stripped of their contents. Occasionally the vesicles are much more strikingly involved than the prostate which remains rather small, soft, and freely movable; in that case the rectal massage is confined particularly to the vesicular stripping. Following rectal massage urethral irrigations—at first to the anterior urethra—should be continued, together with the injections. This is done to limit any more extensive involvement of the urethra, and to gradually overcome that which always exists there. As the urethral discharge practically disappears and the second and third glasses of voided urine remain cloudy, 4 to 5 c.c. of 10 to 15 per cent argyrol deposited in the posterior urethra by means of the Keys-Ultzman syringe and the excess allowed to flow beyond the internal sphincter into the bladder over the trigone is very helpful. At this time, too, deep urethral irrigations into the bladder allowing the patient to void the

contents when full may very helpfully precede the instillations. Prostatic massage and vesicular stripping when necessary should continue two to three times a week for several weeks—sometimes for several months—or until the voided urine in the three glasses is free from pus and the prostatic smears are several times negative for gonococci. In occasional instances the posterior alone will be involved with the verumontanum enlarged, swollen, hyperemic, and its ducts exuding pin points of pus when viewed through the endoscope. As a rule, these cases have only a minimal involvement of the prostatic ducts, and deep instillations alone will suffice to clear up the infection. After a few weeks' treatment if the cloudy urine still persists, endoscopic applications of 10 to 20 to 30 per cent of silver nitrate to the veru itself is of value. In the more resistant infections fulguration of the veru with the mild coagulating current through the endoscope should be tried.

Very infrequently if our case has been carefully handled and intelligently supervised, do we encounter a stricture of the urethra, except where stricture exists as the result of a previous infection. When such is the case, however, the discharge when possible should be reduced to a low level by irrigations and injections before we institute dilation of the constricted area with the leaded flexible bougies. In the more intractible of strictures it is sometimes necessary to do an internal urethrotomy, preferably with the Maisonneuve urethrotome, before satisfactory drainage can be obtained.

In all cases of chronic gonorrhea several dilations of the urethra with the flexible leaded bougies up to 24° to 26° F. and then with the Kollman dilator is a well-chosen procedure to insure a patency of the openings of the prostatic tubules, and also a normal-sized anterior urethra. This procedure naturally should follow, unless otherwise indicated, after we believe the infection is eradicated, or at least reduced to a very low level.

Throughout the course of any urethral or associated infection an increase in the fluid intake is beneficial—eight to ten glasses of water a day should be advised and an effort made to keep the reaction of the urine as near neutral as possible. As to medication by mouth in the gonorrheal infection that has become chronic, there is

very little of proven value available. The balsamics by their presence in the urine and their effect on the posterior urethra may exert a slightly soothing action which hastens the curative effect of the local measures indicated. Acriflavin in tablet form, 1 to 2 gr. three times a day after meals, has sometimes appeared to have an inhibiting effect when the cloudiness involves the entire three glasses. Alcohol in any form or in any amount has no place in the diet of the chronically infected gonorrheal patient.

For the most part we may accurately consider chronic gonorrhea as a local infection, in which one or more structures may be involved. The vaccines, foreign proteins, hyperthermal applications to the urethra, and the bacteriophage, with our present knowledge, appear of value not as routine procedures, but in the exceptional case when our best directed local efforts have failed to bring about a germ-free cure in a reasonable time.

In gonorrheal arthritis the polyvalent vaccines or better still a vaccine made from the patients own strain of organisms are of definite value in supporting any local treatment.

The surgical complications of chronic gonorrhea are infrequent. In general practice one may work a lifetime and never encounter an abscess of either seminal vesicle or even a prostatic abscess. In involvement of the epididymes, too, incision and drainage should be reserved for the unusual case and reliance placed on palliative measures of rest, heat in the form of diathermy, and increased fluid intake for the average case.

Many additional drugs could easily be mentioned, other quips and quirks could be emphasized in local treatment, and many minor and some major surgical procedures could be graphically described. In the exceptional case an unusual but therapeutically sound procedure may be drawn from the experience of the past to aid us, but the thought always should be to obtain an accurate anatomical diagnosis of the parts involved, and then to proceed with gentleness employing procedures of proven value and at least leave our patient no worse than when we found him. Many a stricture and fibrotic prostate of the present not to mention an irremedial sterility can be traced back to ill-advised, heroic, and too rapid therapeutics of the past.

GONORRHEA IN THE FEMALE

R N RITCHIE M D

Associate Professor Obstetrics and Gynecology, University of Rochester School of Medicine and Dentistry Rochester

Considering the prevalence of gonorrhea in women, the intractability of its local processes, and its far reaching influence on the health and bodily resistance of the individual, it must be regarded as one of the most important gynecologic diseases. Because of the anatomical arrangement of the female genital tract, the disease in women is far more varied and difficult to treat than in men.

There have been many papers published dealing with the frequency of the condition. Some grossly overestimated, others underestimated. Noeggarath's sensational paper in 1872 stating that 80 per cent of married men and as many wives had acute or chronic gonorrhea in New York is an example of the former. Like so many who become absorbed in a topic, those who have interested themselves in this subject, are liable to lean backward and unconsciously overestimate actual figures.

Gonorrhea has an unusual standing among infectious diseases, not only in its clinical manifestations, but also in the fact that its specific organism, the gonococcus, has certain special characteristics that differentiate it from all pathogenic bacteria. The microscopic appearance and the morphology of the gonococcus cannot be dealt with in this paper, as we are chiefly interested in its clinical manifestations and treatment.

It is well known that there is no immunity whatever, either from previous attacks or by individual resistance such as belongs in some form to most other organisms.

The gonococcus finds its place of abode in mucous surfaces, where it lives for the most part superficially between the interstices of the epithelial cells, and as a result spreads by contiguity from cell to cell. It has little tendency to invade the lumina of deep-lying glands, such as those of the cervix and the vulva, but confines its activities to the glandular ducts, nor does it have a tendency to penetrate into subcutaneous connective tissue, nor invade the lymph and blood channels, although it may do all of these things occasionally. As we anticipate, it attacks the joints and the valves of the heart, and a few cases of general gonorrheal

septicemia have been reported. The organism has a special predilection for certain mucous surfaces and when it comes in contact with these surfaces grows immediately in the same manner as do other bacteria on their favorite culture media. No abrasion or injury of the tissue surface is necessary, the normal, uninjured epithelium being sufficient for its life and reproduction. When confined in occluded spaces like that of a sactosolpinx, the gonococcus soon dies, whereas in unrestrained secretions it retains considerable longevity and virulence.

The gonococcus is a human parasite exclusively. It is not found outside the human body, nor can it readily be inoculated in other human tissues, its culture media must be made from human secretions. As a result of this tendency methods of treatment are difficult and painstaking. The gonococcus is extremely sensitive both to heat and cold, a slight deviation one way or the other will destroy its growth. It is readily crowded out by other organisms. It is not readily killed by most antiseptics. On account of its tendency to invade the epithelium of tissues on which it grows, it is necessary to use such antiseptics as have the property of penetrating epithelial cells without damaging the normal tissue. Examples of these antiseptics are numerous, *e g*, many silver preparations, iodine, permanganate of potassium, and methylene blue, mercuriochrome, Dakin's solution. These antiseptics are not effective in the presence of serum.

Another point of clinical importance is that it grows on moist surfaces. Under dry conditions it soon dies. If the surfaces are constantly moist, such as in the genital tract, the organism lives, but is temporarily inactive. In other words, the patient has gonorrhea without symptoms. Its lurking characteristics keep it safe from injuries which do not destroy the epithelial cells between them, so that it may remain dormant for long periods of time until stimulated into activity by changes in the circulation of surrounding tissue. The limit of latency is a conjecture—probably 3 to 4 years in men, and 4 to 6 years in

women, but this is open to discussion. Re-infection is the problem under such circumstances.

The favorite lurking places for latent gonococci are in secluded and well-protected folds of certain tissues for which they have a predilection. Examples of these are the prostate gland in the male, and in the female Skene's tubules, the ducts of the cervical and vestibular glands, and the lining of the fallopian tubes. The latent germ may light up into acute activity in several ways: It may produce a fresh attack in the individual in whom it has been residing as a latent parasite, or it may be transferred to another individual and, finding there a fresh soil more congenial to its growth, incite a new process. The condition that favors an awakening of a latent gonorrhea most is the transferring of fresh nourishment to the tissue on which it exists as a result of hyperemia, such as may be brought about by excessive intercourse, menstruation, childbirth, and operative procedures. It is this power of latency which makes the gonococcus so treacherous an organism, makes its treatment so difficult, and which renders so futile the efforts to prevent the extensive ravages that the disease makes on the health of women.

According to many, the gonococcus does not pass through a true incubation period but begins to grow and multiply in a very short time after being transplanted. The reaction in the tissues appears within from 12 hours to 2 days, and according to some writers, never more than 3 days. The tissue requirements for the active development of the gonococcus are that it be soft, delicate, continually moist, and well supplied with blood. The epithelial surface it attacks is varied—modified epithelium like that of the urethra, delicate squamous epithelium of the vagina, or it may be cylindric mucous epithelium like that of the endocervix, or it may be the meso-epithelium of pelvic peritoneum.

When the gonococci have gained their foothold on the surface of the epithelial cells, the inflammatory reaction of the tissues begins at once. The capillary blood vessels are distended and through the walls wander great numbers of leukocytes into the connective tissue. These are followed by lymphocytes and plasma cells. There soon takes place from the epithelial surface an exudate which is at first serous, but later becomes purulent. The sub-epithelial edema and swelling causes

necrosis and desquamation of the surface layer, resulting in small ulcerations.

The discussion of this problem up to the present concludes that the surface epithelium of the various parts of the female genital system offers favorable soil for the growth of the gonococcus, and the infection of each one of these parts constitutes more or less a special disease requiring special treatment, and which may exist as an affection by itself or be associated with infections of other parts of the genital tract.

The parts of the genital tract which may be infected are as follows:

1. Skene's ducts or para-urethral glands.
2. Bartholin glands.
3. Endocervix.
4. Endometrium (rarely).
5. Fallopian tubes.
6. Ovaries.
7. Pelvic peritoneum.

A short discussion of the involvement of these parts will aid in a better understanding of some of the modern methods of treatment which will be discussed shortly.

The Skene's ducts are the small secreting structures on each side of the meatus of the urethra. An inflammation of these ducts is pathognomonic of gonorrhea as they are rarely infected by any other organism. The ducts appear inflamed, the meatus is swollen and red, and the ducts, which are normally not discernible, are distended and pouting, and a characteristic exudate may be expressed. The disease of the glands usually ceases with a healing process, or the infection becomes more or less constant. A virulent strain of the gonococcus manifesting itself with a positive smear. Following treatment for a considerable length of time, the infection may become mixed, which frequently happens, and then the process becomes chronic, the gonococci being crowded out by the other organisms. Nevertheless, the primary lesion was caused by the gonococci. If the secondary infection predominates, small pus pockets in the urethral meatus are formed, and there is a constant irritation. Sometimes the process burrows more deeply into the tissue and causes a peri-urethral abscess with an opening into the urethra resulting in periodic discharge of pus into the urethra. Because of not always obtaining a positive smear under such conditions, the condition is frequently at-

tributed to some other cause. We are not familiar with any other cause which will produce such clinical symptoms and pathological findings in the urethra. One must always remember that negative smears are the results of the gonococci being crowded out by other bacteria. This point cannot be too strongly emphasized in determining the etiological factor causing the infection. The author stresses the importance of examining the meatus of the urethra carefully for infection, as it is frequently overlooked in searching for infection in other parts of the genital tract, and not finding the primary lesion, the diagnosis is missed; and later when the infection has spread, the involvement is frequently beyond repair. Not only must it be carefully examined, but exudate must be expressed from the ducts and several smears taken to rule out the gonococcus, more particularly if the infection is recent with slight urinary symptoms.

The Bartholin glands may be infected primarily, but the infection is usually secondary to an infection elsewhere, especially the urethra. They are rarely infected by any organism other than the gonococcus. Accordingly, any inflammation of them constitutes almost a positive stigma of gonorrhea. If the infection extends to the main part of the gland, an abscess is formed, or it may be dormant and light up at some later period. The initial infection may pass unnoticed and no evidence of disease in the gland appears until long after other manifestations of gonorrhea have disappeared. Inflammation is almost sure to recur if the gland is not entirely excised. Recurrence may take place some years after the initial infection.

The clinical picture, both subjectively and objectively, is characteristic and needs no further discussion. The important point in treatment is not incision of the gland, but excision. Frequently we hear discussed the congenital cysts of the Bartholin glands. These are rare and what actually occurs is that the duct has become occluded as a result of initial gonorrheal infection. Secretions of the gland cause a retention cyst which appears long after the first infection. As a result of this pathological change, we look upon cysts of Bartholin glands as the result of an old gonorrheal infection, and this condition is to be regarded as a fairly reliable stigma of the disease.

The vagina in a sexually mature women

is rarely the primary seat of gonorrheal infection. It takes part in the general inflammation particularly in young girls, becoming swollen, red, tender, and bathed in pus. It is very amenable to treatment which will be discussed under the general treatment of gonorrhea.

In order to understand cervicitis, we must have some knowledge of the histologic anatomy of the cervix in its normal state. The membrane lining the genital canal of the vagina, cervix, uterus, and tubes has a common origin and constitutes the so-called Mullerian epithelium. The Müllerian epithelium in its final development is not uniform, but takes on specific modifications in each of the organs of the genital tract in order to meet the different functional requirement. Naturally from this anatomical arrangement when the vagina becomes involved, the vaginal portion of the cervix cannot escape and becomes the most intensely inflamed part, being red, swollen, and angry looking. In a short time the endocervix becomes involved and the cervix becomes hypertrophied, the glands cystic, and the edges of the external os show evidence of erosion. As a result of the involvement, it must be our purpose to prevent the acute stage from spreading into the endocervix, as in this location we are dealing with a chronic cervicitis, the results of an acute gonorrheal infection which is difficult to treat and is the cause of so much destructive surgery for the eradication of a chronic condition. The unfortunate part of acute gonorrhea of the cervix is that it gives no symptoms other than a leukorrheal discharge, and the time immortal treatment with douches relieves the discharge for a time and the condition is neglected on account of the absence of pain, which we never have associated with acute cervicitis per se. As a result of this neglect, we now have developed a special disease of the cervix which is of great clinical importance. We are now dealing with a mixed infection as found in Skene's and Bartholin's glands. The gonococci are crowded out by other organisms and the infection is carried into the lumina of the racemose glands of the cervix. The irritation of the infection stimulates the mucous cells to hypersecretion so that a stream of mucopurulent material is continually poured out into the cervical canal, thus producing a constant leukorrheal discharge characteristic of the disease. The glands continue to secrete without an outlet and

thermal death time is divided into 3 groups:

1. Group sensitive to heat, much less than thermal death time is required.
2. Moderate sensitivity to heat, a good part of the period is required.
3. Very resistant sensitivity to heat, full thermal death time is required. This grouping probably explains some of the failures.

We have had 61 cases with different thermal death times. So far, Dr. Warren feels that we are dealing with many strains of gonococci.

Positive smears were easy to obtain, but positive cultures were more difficult, although it is easier to obtain a positive culture from a female than a male. In the case of a negative culture with positive smears, the culture was repeated and if still negative, the patient was given 5 hours of general fever treatment as a routine procedure.

Dr. Warren felt that this was a strenuous treatment for each individual patient and devised a modified Elliott treatment, going one step further by determining the thermal death time of the gonococcus from each individual patient. He inserted a metal applicator into the vagina with a to and fro continuous water flow. This was attached to an electric pump which kept the water flowing into a container in the vagina for any length of time desired. The temperature, regulated by a constant tem-

perature bath, was kept at 43.5° C. We term this local heat treatment. Water at 43.5° C. is safe but at 44° C. burns. The duration of time for this treatment has been 60 to 100 hours. Thermal death time of the gonococcus for this group, which was resistant, was 18 to 24 hours. In 15 cases the cures were 50 per cent. The remaining 50 per cent were given general fever treatment for 5 hours and then local heat treatment for 60 hours several days later. It is too soon to give correct figures on this group, as the work is still being completed. For complete details of this work, the reader is referred to the articles by Dr. S. L. Warren and Dr. Charles Carpenter, Associate Professor of Bacteriology, which appeared in the *American Journal of Medical Sciences*, 1933, the *Journal of Experimental Medicine*, and the *Journal of Laboratory and Clinical Medicine*. Other articles will be published shortly.

In conclusion we believe that studying the thermal death time of gonococci is the method by which we can classify the strain and thereby adopt a treatment according to its sensitivity, whether it be by the heat method described or some other. We have known that the gonococcus is destroyed by marked variations in temperature, and this method of approach has great scientific possibilities, although it is still in its early development.

DANGEROUS FAT REDUCERS

The "reducing racket" has a group of new and dangerous drugs, dinitrophenol and related compounds. Racketeers are selling these drugs as fat reducers in spite of reports of deaths caused by their compounds, says W. G. Campbell, Chief of the Food and Drug Administration. "Reducing-agents containing these drugs," says Mr. Campbell, "have sprung up like mushrooms all over the country, and are endangering the lives of patrons. The Federal Food and Drug Act has no jurisdiction over products of this type, dangerous though they may be. All that the Food and Drug Administration can do is to warn the public that these compounds are dangerous."

Clinical evidence shows, Mr. Campbell said, that these drugs act by increasing the metabolic rate. This amounts to a speeding up of the body process, resulting in a destruction of the tissues, including fat, to provide fuel for the accelerated metabolism. Common symptoms are increased temperature, pulse, or respiration, or copious sweating. In particular, Mr. Campbell

warned, these drugs should not be used by individuals suffering from chronic rheumatism, alcoholism, tuberculosis, or diseases of the heart, liver, or kidneys, as poisonous and otherwise harmful effects are even more likely to manifest themselves. There is also some evidence that they may cause profound disturbances of the blood-forming organs.

These drugs, in common with many others, may serve a useful purpose when the dosage is properly adapted to the needs of the individual patient, provided there are no contra-indications to its use, he says. Proper dosage and indications for use, however, as well as prompt discovery of toxic effects, can be determined only by a skilled physician. Furthermore, there may be unexpected harmful effects that are not disclosed by the first tests. Such effects can be determined conclusively only after extensive trial and use, in addition to the tests which should in all cases be made before the preparation is offered to the public.

MINOR COMPLAINTS OF PREGNANCY

CHARLES J. MARSHALL, M.D.

Binghamton

The so-called "minor complaints" or symptoms of pregnancy were studied in 165 consecutive private patients. 116 of them were primiparae and 49 multiparae. These have been subdivided into the following groups with the percentages of cases of particular complaints.

ABDOMINAL PAIN (83 per cent)

Blakely¹ in a recent study found that 85 per cent of his pregnant patients had abdominal pain.

This pain was usually located in the lower abdomen. During the first trimester the corpus luteum of pregnancy often caused pain in the right or left lower quadrants. It usually disappeared at 4 months. (This complaint, and the nausea and vomiting of pregnancy, may cause a mistaken diagnosis of appendicitis.) Occasionally, if vomiting was frequent, there would be some distress in the epigastrium, possibly due to cardiospasm or slight liver necrosis.

During the latter months, discomfort was present more often over the lower lateral surfaces of the uterus, and in the inguinal region. Probably this was due to the stretching of the round ligaments as the uterus enlarged. Sometimes, with slight torsion of the uterus, the pain would be more severe over one ligament. Lying upon the painful side relieved it. Braxton-Hicks contractions during the last two months were occasionally painful. In one breech case a tender area was felt over the right cornu of the uterus, which disappeared immediately when spontaneous version took place.

Unrelieved constipation and gas distention of the colon caused pain in the region of the hepatic and splenic flexures. Pain and tenderness over the gallbladder was not infrequent, and in three instances it was proven to be due to cholelithiasis. Higgins and Mann² claim that the emptying of the gallbladder was much delayed in some pregnant animals.

"MUSCLE CRAMPS" (68 per cent)

"Muscle cramps" or "tetanoid" contractions of the muscles of the lower extremities were most frequent during the night and early morning, before arising.

At times the spasm in the foot would resemble the contractions seen in true tetany. Seldom were cramps present in the upper extremities. One patient stated that her father was subject to muscle cramps of the feet and legs throughout his entire lifetime. She had them daily throughout her pregnancy, and also during labor.

In over 50 per cent the onset was during the first two trimesters; a few in the first trimester. This fact probably refutes Adair's³ statement that they are "due to muscle strain in nature's effort to maintain the body balance as the center of weights shifts forward." Hartley⁴ mentions them as part of a "tetanoid state," possibly due to a disturbance in the calcium metabolism. In several severe cases he obtained good results using calcium and parathyroid therapy. The parathyroid glands apparently hypertrophy during pregnancy, indicating that possibly an increased secretion is needed.

Hartley⁵ also reports that he can predict "muscle cramps" beforehand if the patient has had severe menstrual cramps previous to pregnancy. Thirty cases in my series had had menstrual cramps, but only 10 of them had "muscle cramps" often, and 10 others occasionally.

Walking and brisk massage of the leg were most beneficial. In this series the use of calcium gluconate 120 gr., 1 qt. of milk and viosterol, min. xxx, daily, seemed of very little benefit. Richardson⁶, however, claims that he had good results with similar therapy.

BACKACHE (60 per cent)

Backache seemed to be due to several causes. Strain of the lumbar muscles and the vertebral ligaments, due to a change in the center of gravity was often responsible; fallen arches aggravated the complaint. It was relieved by rest in bed. A maternity corset with moderately rigid stays in the back was of benefit.

Some severe lower lumbar and sacral pain was a referred pain from the enlarging uterus, occurring most frequently during the last three weeks of pregnancy. Rest and other treatment did not relieve it.

Sacro-iliac relaxation as evidenced by pain over the joint was usually unilateral and was often referred along the sciatic nerve. Usually a maternity corset would relieve it. This corset should have a strap or other device that will pull it snug over the sacro-iliac region. Also the patient's bed should have wide boards, placed transversely, between the mattress and springs. This flat surface is more comfortable for her to lie upon.

Mid-dorsal pain, with tenderness over the vertebrae and corresponding intercostal nerves was probably of rheumatic origin. Foci of infection in the teeth or tonsils were often found as a cause.

Pain and tenderness elicited in the costo-vertebral angles, radiating anteriorly and along the course of the ureters, probably were due to pyelonephritis. Pus was found in the catheterized bladder specimens in each case. Frequently an acute nose and throat infection aggravated the pain and other symptoms. Sodium citrate was used with some relief of frequency. The urinary antiseptics seemed to have very little therapeutic value in clearing up the pus in the urine. Heat would temporarily relieve the pain.

NAUSEA

Primiparae, 81 per cent

Multiparae, 65 per cent

The nausea of pregnancy was one of the most distressing of the many complaints. A multitude of theories and a dearth of real facts make one hesitant to mention a cause. Alvarez and Hosoi⁷ suggest that the reversal of gradients in the bowel may account for it. This suggestion does not explain why nausea is usually more severe in primiparae. They also suggest that the woman learns to overcome it as a sailor learns to overcome seasickness. As a rule, in these cases, however, the nausea seemed in many instances to improve almost overnight. Often also the death of the fetus and placenta is signalled by the cessation of the symptom. These facts possibly point to some toxin, secretion, or other substance elaborated by either the placenta, the fetus, the ovaries, or one of the ductless glands, most likely the placenta. Is it possible that an anti-toxin is formed to combat this "toxin" or "secretion?"

Kramer-Petersen⁸ and others have found that a hypochylia and hypo-acidity are

present during pregnancy in cases with emesis. The feeding of different acids, although it did not cure the nausea, seemed, in my series, to allow food to be better tolerated. Twenty minims of dilute hydrochloric acid before each meal was sometimes of benefit. Vegetables flavored with vinegar or lemon juice, lemonade, and orangeade seemed to be retained much better than many other foods. Of late, carbohydrate feedings have been the vogue, but they should not be in the form of candy, as sweet-tasting food is the least well tolerated. Frequent, small meals and effervescent drinks between meals, in sips, were given. Rest in bed was the most satisfactory treatment of all. Sodium amytal, gr. 3, by mouth, or gr. 6, per rectum, was occasionally used in the morning upon awakening, to overcome the "nervousness." Corpus luteum, given subcutaneously, appeared to be worthless.

"HEARTBURN" (45 per cent)

So-called "heartburn" was rarely present during the first four months of gestation, but often troubled the patient the last five months. As yet no satisfactory explanation of this complaint has been made. There is no proof that gastric hypersecretion or hyperacidity is a cause. Kramer-Petersen⁸ examined the gastric contents of 90 normal pregnancies, but the vast majority had a hypoacidity or achylia. Some "heartburn" was possibly due to a regurgitation of gastric secretion, which caused a substernal burning sensation. Nevertheless one would expect that this symptom was due to hyperacidity or hypersecretion inasmuch as treatment for hyperacidity relieved it. Many of these same patients had a voracious appetite. Was the appetite caused by hypersecretion, or did overeating bring on a hypersecretion? I suggest that the former was responsible.

To prevent this discomfort certain foods were avoided, namely, fried food, sweets, highly spiced meats, lemonade, onions, radishes, raw apples, coffee, and meat soup. Milk seemed to relieve it. An antacid powder containing bismuth subcarbonate, 15 gm., magnesium oxide (light), 10 gm., and calcium carbonate, 15 gm., taken one hour after meals in teaspoonful doses was very helpful.

CONSTIPATION (73 per cent)

The cause of constipation in pregnancy was formerly thought to be due mostly to

pressure on the bowel by the enlarging uterus. Probably the uterus hinders bowel action instead by displacing the cecum and the sigmoid colon slightly. Many believe to-day that the enlarging uterus causes no increase in intra-abdominal pressure. Guthmann and Stahler⁹ found a diminution in tonus of the entire gastro-intestinal tract during the last trimester. Alvarez and Hosoi⁷ have found that peristaltic rushes were inhibited in pregnant rabbits and often reversed peristalsis was seen. The theory of atony of the bowel as a cause of constipation seems plausible. Possibly large doses of pituitrin would overcome this atony, but I have not had the courage to try it in pregnancy.

Early in pregnancy the patient eats less food, due to her nausea. Possibly this is also a slight factor.

The treatment used in this series followed usual lines. Early in pregnancy laxatives in pill form such as phenolphthalein or cascara, supplemented by an occasional enema, were used. After the disappearance of nausea, mineral oil in some form was given at bedtime, with occasional cases requiring the addition of cascara, phenolphthalein, or milk of magnesia.

CERVICAL BLEEDINGS (3 per cent)

In some of these patients it has been observed that the epithelium of the cervix had undergone considerable proliferation. The epithelium was heaped up in ridges instead of lying flat and smooth, and partially overlapped the external os at times. Furrows were present between these ridges, which ran in a more or less radial manner, and they were deeper on the anterior lip. Hofbauer¹⁰ has recently found that in some cases "solid tongues of proliferating epithelial cells in discrete places of the cervical mucosa" are produced. This hyperplasia was noted in all cases of this series who had any cervical bleeding, and also in a few who had no evidence of bleeding. Biopsy in one case showed hyperplasia of the mucosa. Another case was reported as having a decidual reaction. Two cases had an "erosion" of the cervix present since a previous pregnancy. V. Stieve¹¹ found hyperplasia of the mucosa of the canal and a great increase in the number of blood vessels.

A slight touch with an applicator would start a flow of blood, when this hyperplasia was present. Also slight trauma, such as

sexual intercourse, was followed occasionally by a slight spotting of blood. Ten per cent silver nitrate applied to the area was usually sufficient to stop the flow. In one case rest in bed was also necessary. It was deemed advisable to prohibit coitus in all cases with a cervical erosion or with epithelial hyperplasia.

"VAGINAL DISCHARGE" (PROFUSE) (13 per cent)

A slight increase in the vaginal secretion is normal. Occasionally, however, a vaginitis developed, which caused a profuse and irritating discharge. *Trichomonas vaginalis* infection is supposed to be the most common cause, but it has not yet been definitely proven to be the primary invader, and the parasite is often found when there is no vaginitis. The vaginitis seemed to occur most frequently in obese women in my cases. The appearance of the vagina resembled clinically the vaginitis supposed to be due to the trichomonad. In 3 cases, however, it was due to the gonococcus, and one case was associated with a vaginitis emphysematosa.

Several methods of treatment have been used, but the most efficacious was as follows: morning and evening douche with sterile 1 per cent sodium bicarbonate solution. The vagina was scrubbed with tincture of green soap and painted thoroughly with a 10 per cent aqueous mercurochrome solution every other day. The patient was instructed to keep a small ball of cotton between the labia minora to collect the discharge before it reached the skin of the vulva. This cotton was changed frequently and was held in place with the ordinary vulva pad.

EDEMA (74 per cent)

Several factors are apparently responsible for pregnancy edema. Loss of tone of the venous system with a resultant sluggish flow of blood may cause a "back pressure," in the capillaries. Kaboth¹² found a change in ratio of the blood colloids, serum albumin, and serum globulin, resulting in a lowered osmotic pressure. The blood colloids apparently regulate fluid exchange, and this change seemed to be greater during eclampsia and nephrosis. Pressure by the enlarged uterus probably is not a factor at all, as slight edema is frequently present in the hands as well as in the feet.

In this series there were five twin pregnancies, and three of them at eight months

had only slight edema. The other two had considerable edema of the feet and hands, but it was associated with a pre-eclamptic toxemia. Likewise one case of polyhydramnios had only slight swelling of the feet. It would seem plausible that the uterus exerted no pressure in those complications.

Nephritic or preëclamptic toxemia was present in over one-half of the patients who had considerable edema. Heat seemed to increase the amount of swelling, possibly by causing venous and capillary dilatation.

Although the blood chlorides are usually normal or slightly lowered during pregnancy, occasionally a salt-poor diet seemed to be of benefit. Also one or two drams of magnesium sulphate daily relieved the edema to a considerable extent. Rest in bed caused an apparent diminution of swelling in the legs, but the fluid probably gravitated to the back, abdomen, and hands.

VARICOSE VEINS (18 per cent)

It was formerly believed that varicosities of the lower extremities were due to uterine pressure upon the external iliac veins, and to the lack of sufficient valves in the superficial veins in the lower extremities. However, late in pregnancy the uterus is an abdominal organ, and the thin lower uterine segment probably does not even press slightly upon these veins. Jaggard¹³ believes "that the pregnant uterus even at term could not directly compress the ureters, and that if it did, the pressure would be no greater than that of the intestinal mass." The specific gravity of the uterus and intestinal mass are nearly the same. Therefore if the uterus cannot compress the ureters, it seems plausible that it cannot exert much pressure on the iliac veins. Kilbourne¹⁴ believes that a lack of tone is present in the whole venous system, possibly due to a posterior hypopituitarism. Several in my series have noted, without questioning them, that the veins of the forearms and hands were more prominent.

Also, Kilbourne has proven that a tourniquet applied just below the knee does not hinder the venous flow upward in the deeper veins. He injected ipax in the superficial veins of the leg, and by roentgenograms observed the flow to be downward and into the deeper veins of the leg. Therefore round garters or a bandage placed just above or below the knee may be of benefit by preventing back pressure

from the venous blood column above the knee. In 3 patients of my series an elastic cloth bandage was applied in a spiral around the leg; snug below the knee and loose at the ankle. This method of application seemed to relieve the pain, but no diminution of the edema was noted.

In one of this series spontaneous thrombosis of the superficial veins caused considerable relief from pain. McPheeters¹⁵ injected 92 cases during the fifth month, with good results. Probably we should occasionally use this method of cure if bandaging does not relieve the severe pain but most should be left until after pregnancy has terminated as many become much improved then and treatment becomes unnecessary.

INSOMNIA (15 per cent)

The inability to sleep was more often due to "nervousness" or worry over various problems than from any other cause. This was most common in those women who suffered "hysterical" symptoms such as numbness of the extremities, dizziness, and fainting. Elixir of phenobarbital, drams 2, was very beneficial if given one-half hour before bedtime. Warm baths and drinks seemed of very little benefit. Muscle cramps would awaken some patients, for a few moments, but in only two instances was this a cause of considerable loss of sleep. Pruritus vulvae was a cause in two instances, and general pruritus due to herpes gestationis was the cause in one instance. The latter was very intractable and no permanent relief was found for the pruritus. During the last month of gestation, Braxton-Hicks contractions were painful enough to awaken a few for short periods of time. Sodium amytal, gr. 3, or ortal sodium, gr. 3, would relieve them.

THE PHYSICAL THERAPY DEPARTMENT IN A HOSPITAL

FREDERICK E. BAUER, M.D.
New York City

The necessity for a physical therapy department or clinic in any general hospital, either small or large, is recognized not only by the medical profession but by the general public as well. The average patient when entering a hospital expects that every possible means for the alleviation or cure of his trouble will be supplied, and certainly a well-organized and equipped physical therapy department is one of these. The enormous extent to which physical therapy measures were successfully utilized in our war hospitals caused a nation-wide realization of the value of such measures.

The writer will attempt to outline briefly the necessary steps to be taken in the organization of such a department. The first consideration is location. Sufficient space should be allotted for the purpose to allow for growth. As a rule, after the establishment of such a department, the number of cases referred to it by the general staff and from the various clinics increases very rapidly; and, unless adequate space has been provided, there will be overcrowding and a drop in the quality of the treatments administered. The space utilized should be well lighted and ventilated, preferably on or above the ground floor, as a large proportion of the patients are crippled or in pain and easy access is desirable. The necessity for good ventilation appears when one considers the amount of heat liberated by the various thermal units, and the necessity for a plentiful supply of fresh air is evident when one considers the usually crowded conditions of such departments; this is especially necessary where carbon arc lamps are used as a source of actinic radiation. The waiting room should be separate from the examination and instrument rooms, should have ample seating accommodation, and a lavatory provided.

The necessary equipment varies according to the size of the unit and the type of work undertaken. But a certain minimum is necessary if the unit is to function creditably.

A high-frequency machine for the administration of diathermy, autocondensation, electrocoagulation, fulguration, etc.

A low-frequency machine for galvanic and faradic treatments, muscle and nerve testing, and ionization.

Some source of radiant heat—the carbon filament lamp or the infra-red lamp—as a matter of fact, all radiant heat, whether luminous or not, consists largely of infra-red waves.

A source of ultra-violet radiation; either a mercury arc in a quartz tube or a cold quartz lamp, which consists of a bulb containing gas which is ionized by a high-frequency current flowing in a coil surrounding the bulb. The carbon arc lamp is likewise a well-known source of actinic radiation.

There should be treatment tables, an autocondensation pad, a protractor for measuring gain or loss of motion in a joint, and a sphygmomanometer for testing blood pressure when giving autocondensation.

The larger units should consist of sufficient apparatus to take care of the volume of work. This should include additional equipment such as the various exercising machines, vibrators, sinusoidal machines for electrical stimulation and passive exercise of muscles, and a well-equipped hydrotherapeutic unit. An arm and leg whirlpool bath is very useful, even in small units. The author believes a static machine of at least 12 or 16 plates should be part of the equipment in every physical therapy department. There is no other means which will so quickly allay pain and swelling in acute traumatic conditions.

PERSONNEL.—The selection of a qualified personnel is extremely important. The medical board of a hospital cannot use too much care in the selection of a doctor who is to take charge of the physical therapy department. The physician who has served his internship in a hospital, who has had a number of years in general practice, who is familiar with the ills, real or fancied, of the average patient, and then has studied under recognized authorities the physical means by which disease can be combated—a man who not only understands the pathology of the conditions he is to treat, but also something of the physics of the machines he will use in the treatment of disease and disability, is properly qualified to take charge of a physical therapy department. His assistants should be young men who are interested in this particular field

and are willing to devote time and study to the problems it presents.

The most important person after the head in a physical therapy department is the chief massage operator. Great care should be taken in the selection of a suitable person—one with thorough training and experience, with capable hands that can feel the least contraction of a muscle, that can differentiate edema, fibrosis, and spasticity.

The technicians employed, as well as the physicians, should be fully aware of the possibility for harm in the use of the various machines. A little carelessness in the use of actinic light or an improperly applied diathermy electrode may be the cause of severe burns and unpleasant legal complications.

RELATIVE STANDING OF PHYSICAL THERAPY DEPARTMENT.—In considering the great variety of cases that are referred to the physical therapy department and the very special training required for it to function successfully, it becomes obvious that the department must stand on an equal basis with the other major departments of the hospital, surgery, internal medicine, etc., and its head ranked accordingly.

The physician in charge of the physical therapy department should designate the treatment in all cases, as he is responsible for the results and, by reason of his special training, is best qualified to do so. If the referring physician desires a certain treatment given and it is approved by the physician in charge, it is all right; but if the physician in charge does not consider it advisable to give the suggested treatment, or is of the opinion that some other treatment would be more effective, he must be free to use the treatment he considers best. If the referring physician insists on the treatment he recommends being given, then the physician in charge, in order to protect himself, should require a signed order. All cases should be examined after six treatments have been given and condition noted. If no clinical improvement has occurred, it may be wise to change the treatment or send the patient to the referring department for reexamination and diagnosis. After thirty treatments, if no improvement has occurred, the referring physician and the physician in charge of the physical therapy department should make a joint examination of the patient and consider what further measures should be taken.

RECORDS AND FILING.—Every hospital usually has its own method of keeping and filing records.

The system used in the municipal hospitals of New York City is probably as simple as can readily be devised and as comprehensive as needful.

REQUEST FOR PHYSICAL THERAPY.—The first record is filled out by the referring department giving brief history of case diagnosis and X-ray findings, if any, and is signed by the referring doctor on the upper half of the record; the lower half is to be marked "Physical Therapy Department" and to be filled out by the physician in charge of that department, designating the kind of treatments to be given and how often. Spaces are left in which to record the total number of treatments given and the result obtained on completion of treatments.

This record is to be filed in the Physical Therapy Department under the name and hospital number as the permanent record of the case.

HOSPITAL RECORD SHEET.—Second, a record sheet of the same size as the case records of the hospital—designated as physical therapy record and containing complete record of kind and number of treatments given and results obtained—to be sent to the referring department and attached to the case record of the patient on completion of the case.

DIAGNOSIS RECORD.—Third, a separate record should be kept of all cases treated in the physical therapy department and listed according to diagnosis, giving kind and number of treatments and results. This record will be found exceedingly useful in preparing reports of results obtained in any given type, in comparing relative value of various methods of treatment and as a record of the number of cases referred from the various hospital departments. This record should be kept in a book on file in the physical therapy department.

Having briefly sketched the organization of a physical therapy department, the author will now try to indicate the relationship which should exist between the hospital staff and the physical therapy department.

The physical therapy department is not to be considered as the spare room in which any and every form of disease and disability that has resisted the usual modes

of treatment can be deposited and forgotten, but as an adjunct, a means of combining the usual methods, including physical therapy; and this cooperation may, and in many cases will be the determining factor in the recovery of the patient. For example, cases of thrombo-angiitis obliterans which so often end in gangrene and amputation should not be shunted into the physical therapy department for treatment two or three times per week or even daily treatment, but should remain in the wards, and the affected parts maintained at a constant temperature two or three degrees above skin temperature and proper medical methods continued. Cases of osteoarthritis, whether of the productive or destructive type, are benefited by physical therapy. Rheumatoid arthritis is a distinct disease and should have medical and surgical treatment as well as physical therapy. Fracture cases should not be deprived of the benefits of physical therapy for weeks. The director of physical therapy is not so much concerned with the solution of continuity of a bone, as with the pathology caused by the traumatism to the soft tissues incident to the fracture.

EARLY REFERENCE DESIRABLE.—If these cases are referred to the physical therapy department at the earliest possible time the surgeon and the physical therapist deem advisable, it may be possible to prevent the exudate, which invariably occurs at the site of such injuries, from becoming organized to a greater extent than requisite for the formation of callus.

Much of the loss of function in fractures is due to fibrosis of exudate interfering with the normal play of muscles in the affected part. And much of the pain suffered is caused by pressure of such organized exudate on the nerves involved.

These cases can be readily treated in the wards, and thus much time can be saved in the restoration of normal function.

Massage and heat can be used in many cases as soon as the fracture has been reduced. Plaster casts may be applied in two sections so that either the upper or lower half may be removed for treatment. Even when a limb is in a traction frame, such treatments can be given. In compound fractures where sections of the cast are cut away for drainage, actinic rays applied stimulate granulation and, if the wound is infected, will aid in its sterilization. Especially in fracture cases that are slow in the formation of callus, actinic rays

applied to the entire body usually stimulate the process and hasten bony union. Likewise osteoporosis can sometimes be stopped by the same means.

In gallbladder cases where there is dysfunction, as shown by the liver function test,—and the author is aware that the dye test does not always show the true degree of dysfunction even if it be present, as enough liver cells may be working to eliminate the dye—but, if marked dysfunction is shown, then diathermy is of value, even a temporary restoration of normal function lessening operative danger. These are but a few instances in which the surgeon and the physical therapist may cooperate. Such cooperation with the medical staff is often equally important. In anemic conditions, for example, other than pernicious anemia, actinic rays are of unquestioned value.

In rickets they are curative, and in tuberculosis of the skin and of the bones and intestines, they should always be used as an adjunct to the medical treatment indicated.

In pneumonia, diathermy eases respiratory movements, slows and strengthens the heart action, and has a general sedative effect; the patient usually sleeps after a treatment; and in the majority of cases recovery is by lysis rather than crisis. In bronchopneumonias which fail to clear up in a reasonable time diathermy will usually hasten the process.

In the rhinological and otological departments of the hospitals the director of physical therapy at times can be of great assistance. A case of chronic otitis media that has been under treatment for months can very often be cured by one or two ionizations of the canal with a 2 per cent solution of zinc sulphate.

HYPERTENSION—The treatment of persistent hypertension by autocondensation in cases that have not reached the stage of sclerosis of the arterial system and the coincident changes which occur in the kidneys, is of the utmost importance. If these cases are referred to the physical therapy department as soon as diagnosed by the medical staff, the hypertension can be reduced and a relatively normal blood pressure maintained. As hypertension is one of the principal causative factors in cardiovascular diseases, the importance of its early recognition and treatment cannot be overemphasized. One should always

have lues in mind as a possible causative factor, and if accurately diagnosed, should resort to the efficient new electrically induced fever treatment.

Cooperation between the gynecological and the physical therapy departments will do much to restore normal conditions in women suffering from pelvic diseases. The majority of these cases are particularly amenable to physical therapy measures. Also in postoperative cases with adhesions which cause pain much can be done.

The use of actinic rays in diseases of the skin has proved its value in many instances, for instance tuberculosis lesions, herpes zoster, erysipelas, impetigo contagiosa, seborrhea, pityriasis rosea, acne, and in some cases of mycotic and parasitic origin.

Last winter an outbreak of impetigo occurred in the obstetric division in Fordham Hospital, every baby becoming infected. Fortunately it was quickly controlled. A quartz lamp was hung from the ceiling, the babies placed on blankets on the floor, cart-wheel fashion, and thus radiated. In less than three weeks all cases were discharged cured, the ward thoroughly disinfected and reopened for service.

Cooperation with the neurological department will be a fruitful field in which to demonstrate the value of physical therapy methods. Considerable advance has been made in the last few years in the use of thermal units to produce artificial fever in various neurological conditions and some striking results have been obtained. The treatment of paralysis following anterior poliomyelitis depends largely on physical measures, exercise in warm baths, the use of sinusoidal currents for muscle and nerve stimulation and corrective exercises.

In this connection should be mentioned a condition that often occurs when treating cases of paralysis in the hospital wards. The best efforts of the physical therapist can be neutralized by an overzealous nurse who insists that the bed clothes be tightly drawn across the foot of the bed and firmly tucked in. When conduction between the

motor nerves and the muscles affected is just beginning to reestablish itself, to bind down the legs and feet so that any effort at voluntary motion is impossible, is certainly deplorable. Demand should always be made that an "L frame be placed under the bedding so that the slightest effort at voluntary motion will be unhindered by either the weight or pressure of the bedding.

DISCUSSION

DR. LEE A. HADLEY: There is very little to add except perhaps to mention the fact that the physical therapy department in a hospital offers a laboratory for clinical research and an opportunity to further the solution of some of the problems which confront this branch of medicine.

One of the problems which has occupied our interest at the Syracuse Memorial Hospital is the development of a technic for recording posture by photographing directly on to bromide paper combining the features of a silhouette and a direct photograph. The latter gives a record of the contours of the body. The patient stands before a black screen, 1,500 watts of light are used, with exposures of three or four seconds. Four pictures are made on a single sheet of five by seven bromide paper showing the patient anterior, posterior and two lateral views; one lateral in the patient's habitual relaxed position and the other in as proper a position as he can be made to assume. We have found that these photographs constitute an excellent record both before and after treatment and stimulate cooperation in the following out of exercises. The cost is less than three cents for each sheet containing four exposures.

Another problem which has occupied our attention consists in the radiation of certain substances to be used as dressings for wounds. Following out some of the work which has already been done petrolatum, mineral oil, olive oil and lanolin were radiated with an air-cooled quartz light. It was found that these substances were capable of taking up and again emitting radiation, the quantities increasing with the substances in the order named, that is, the lanolin gave off a much stronger radiation than the petrolatum. This radiation was invisible and was both taken up and emitted through the glass of the petrie dish covers. It seemed to be just as strong after one hour of radiation as after three hours. The power of radiation appeared to be retained by the substances for a period of weeks.

These are two relatively minor problems but indicate how the physical therapy department of a general hospital may be utilized in a study of some of the problems which confront us.

447 FT. WASHINGTON AVE.

Aroused by the hostile or indifferent attitude of some legislators toward the profession, the Tennessee State Medical Association has created a committee to organize the doctors throughout the State and to effectively contact candidates for governor and the legislature with a view to determining their attitude on issues affecting

medical matters. Already 68 of the 95 counties in the State have been organized. In previous sessions of the Legislature other well-organized groups have made fun of the political impotency of the doctors. Henceforth they will "stand foursquare on well-established principles and fight like men to the bitter end."

New York State Underwrites Milk Campaign

At the invitation of Governor Herbert H. Lehman, about five hundred citizens from various parts of the state attended a luncheon conference at the Ten Eyck Hotel, Albany, on Thursday, July 12th, to discuss the promotion of the use of milk in New York State. A bill advancing a fund of \$500,000 (to be returned by means of a tax of one cent per 100 pounds shared equally by producer and distributor) to promote the consumption of milk in order to improve the wellbeing of the people of the state and to further the prosperity of the milk industry was passed during the last session of the Legislature and signed by Governor Lehman on May 24th, 1934. The luncheon conference was held to aid in carrying out the purpose of this legislation and was attended by groups representing business, industrial, religious, and educational life, and social, economic, political, and health activities, in addition to those directly concerned with the milk industry. Dr. Bedell, President of the Medical Society of the State of New York, Dr. Farmer, Chairman of its Committee on

Public Health and Medical Education, and Dr. Lawrence, the Executive Officer, were among those invited to the Governor's luncheon.

Mr. Frank E. Gannett presided at the conference and the speakers included Governor Lehman, Mrs. Anna Steese Richardson of the Woman's Home Companion, Mrs. Frances H. Blake, President of the New York State Congress of Parents and Teachers, Commissioner Baldwin of the State Department of Health. All speakers emphasized the decrease in consumption of milk in the state, the effects of this on the economic life and health of the people and the advantages to be gained from a state-wide advertising campaign to promote the sale of milk. After the luncheon, ten groups, each representing special interests, held conferences in various committee rooms of the Capitol Building, for the purpose of more efficient discussion of the various phases of the project under consideration.

Members of the medical and nursing professions met in a group with welfare and health officers, and others interested in these fields. A desire to cooperate in the state's plan to increase the consumption of milk was generally expressed. The physician's interest in milk as a necessary food, and his efforts to induce all to use adequate amounts was generally recognized. It was pointed out that the physician could do a great deal of missionary work in the present campaign, by emphasizing these facts at this time to his patients.

The state-wide campaign will consist of three parts:

1. Advertising milk as a commodity.
2. Promotion of the purpose of the advertising campaign through the efforts of various organizations and groups.
3. Publicity from several state departments on milk from various standpoints.

It would seem that all physicians should be acquainted with the objectives of the state's plan. The physician's aid in the campaign will largely be within the second part noted above. He should lend his efforts to promote the adequate consumption of milk for economic as well as health purposes.

Time for Action

President Roosevelt's appointment of a cabinet group to study social reforms during the summer and fall is a clear enough warning signal to those who will be affected by the socialization of medicine. It is, in fact, impossible to mistake it. The committee, we are informed in the Washington dispatches, is "to formulate, with the assistance of expert advisers, a program for submission to Congress, to States, and to governmental subdivisions." And what will their program include? The White House statement leaves us in no doubt whatever. It says that "facts will be gathered and analyzed with regard to unemployment compensation, old-age pensions, workmen's compensation, *health insurance*, mothers' pensions, *maternity benefits*, and insurance against the special hazards of self-employment in small business and agriculture."

The imagination can hardly conceive a more formidable effort to force through Congress, through the state legislatures, and even through the city and town governments (the "governmental subdivisions") a program for the socialization of medical care. The cabinet members appointed to this committee are well known as favoring the socialization of welfare measures. They are to be assisted by an advisory council of fifteen to twenty national leaders in the fields of labor, social welfare, etc., and we can hardly think that an advisory council will be chosen who are hostile to the avowed aim of the plan. The result of their deliberations, then, can be well foretold right now. They will formulate a program of health insurance, and all the power of the national government will be put behind it to enact it into law. One year from to-day may see it a fact.

True, hearings will be held, "to receive the views and reactions of various groups," and "the results of these hearings, together with advice and counsel, will be handed to the President's committee for use in formulating its program," but how much attention they will pay to critics opposing their socialization program may well be questioned.

The final fate of the drive to socialize medicine, among other things, will rest in the hands of Congress, and the entire

House of Representatives and one-third of the Senate will come up for reelection this fall. Before election is the time when the representative of the people is most sensitive to the wishes of the voters of his district. Later, safely elected, the ice of indifference is apt to encrust the waters of sympathy.

In other words, this is the time for the leaders of the county medical societies and other medical organizations to tell the members of Congress, now home from Washington, why the socialization of medicine is ruinous to the profession and leads to a low-grade, inferior medical service to the public. A do-nothing policy, a policy of waiting for others to act, will be fatal. When insurance groups have been formed with streams of money flowing into a central treasury under the control of political appointees, with doctors hired by the year in the same way that school teachers are now, and taking their orders from petty officials ignorant of the rudiments of medicine, then it will be too late to protest. Events are moving swiftly. We cannot and do not believe that this country will embark upon a medical experiment that is contrary to the wishes and interests of the medical profession, but if the profession is silent or inactive, it has only itself to blame for anything that may happen. Now is the time to act.

Health on the Air

A strange jumble fills the air these summer evenings—jazz, grand opera, beauty hints, cookery, baseball scores, farm talks, "Honeyboy and Sassafras," "Three Little Funsters," and advice on health. Much of the program, of course, as the saying is, goes in one ear and out the other, but who can calculate the effect of the continuous stream of health advice that is going out, day after day, to our listening millions? One day's program, taken at random, has three health broadcasts, not counting the talks on food and psychology and the musical numbers that disguise medical advertising. No feature stays on the air programs long if it does not show evidence that people are listening to it, so we may be sure that the nation has its ear

at the radio and is vastly interested in hearing about its health

Here is a situation that demands our earnest attention. Others are already awake to it. Men who chase the dollar with little or no thought of ethics, who are "busily engaged in misleading the public interest in health for private profit" are awake to it. That outspoken phrase was used by a speaker at the Congress on Medical Education in Chicago in February, and he went on to say that the handwriting on the wall warns the physician that he must take up the work of health education if he is to save the public from the fruits of its own folly, and if he is to "retain or regain leadership" among guardians of the people's health.

The gravity of the matter is at once evident to anyone who takes the trouble to read the resolutions adopted by the House of Delegates of the American Medical Association at Cleveland in June. These resolutions note that the various broadcasting companies are permitting the exploitation of many drugs, preparations, "patent medicines," and so called cures over the radio, some of them of merely dubious value and some actually dangerous in the hands of the layman. The symptoms described in these radio broadcasts may indicate serious conditions that call for study by a competent physician to insure the correct treatment before the disease reaches an advanced stage, but the listener is assured that a bottle of this or that nostrum will make all right.

The Federal Radio Commission controls broadcasting and a copy of the American Medical Association's resolutions was sent to it, protesting against the continuance of this misleading and mischievous medical education. Copies were also sent to all members of the Congress and Senate "so that they shall be thoroughly informed of this menace to the health of our citizens, and that they be urged to pass necessary laws to eliminate these dangers."

How much effect this will have on Congress is frankly problematical. To suppose, too, that the broadcasting companies will, in a burst of public spirit, spurn the money of the nostrum makers and banish

them from the air, seems a bit overoptimistic. But the medical societies can do something else, and, in fact, they are doing it. They can oppose bad medical education with good medical education. The radio is being employed widely by organized medicine. We all know the weekly broadcasts of the American Medical Association, which cover the country on a coast-to-coast network, but all may not be aware that at least seventy state, district, and county medical societies broadcast on regular weekly schedules with material furnished by the Bureau of Health and Public Instruction of the American Medical Association. Besides these, others use their own material, and some medical societies use the air occasionally, so that it is calculated that from 125 to 150 medical societies are broadcasting health talks, and virtually every radio set in the land is within the range of the voice of organized medicine.

It is hardly necessary to speak of the vast amount of health material spread upon the pages of the press. Some of the county medical societies are doing a fine work in supplying this matter to their local papers. Speakers, too, are provided to address lay meetings. Taken altogether, we have clear evidence here that the American public is going health muddled in a big way. It presents a golden opportunity to the profession to aid the public health and at the same time to teach correct medical habits and practices to vast numbers found by research to be not receiving medical care. Opportunity is opening wider and wider to the message of health. If we cannot close the channels of the air to the conscienceless exploiters of the sick, let us fill those channels with truth, and trust the intelligence of the public to make the right decision.

A speaker at the recent annual meeting of the South Dakota Medical Association remarked crisply that the history of all schemes that have been tried both in this country and abroad whether they be State Medicine, National Health Insurance, Workmen's Compensation or other show that they all become more or less of a 'racket' to the detriment of both the patient and the physician, the benefits and profits invariably going to the nonmedical racketeers who wax fat on the misfortunes of the patient and the hard work of the physician."

The Medical Society of the County of Rockland

The *Summer Meeting* of the Medical Society of the County of Rockland was held at the Rockland Country Club, Sparkill, on Wednesday afternoon, June 20th. About 40 members of the Society were present.

Dr. William R. Strutton, Pathologist of the Rockland State Hospital, was elected to membership.

The principal address of the afternoon was given by Dr. Samuel J. Kopetzky, of New York City, who is speaker of the House of Delegates of the Medical Society of the State of New York. Dr. Kopetzky's subject was "The Implications of Socialized Medicine."

Dr. Kopetzky pointed out that it was impracticable to socialize medicine in a capitalistic country and that the only way the costs of medical care could be lowered is by "mass production" as in the business world, but this means lowering the quality of medical service. As an example, the state doctors in Europe may examine and treat as many as 50 to 75 patients daily, and as soon as State medicine is established, politics will enter in, resulting in inferior appointments. In socialized medicine the intimate contact of family and physician is lost. Dr. Kopetzky also pointed out that since the institution of socialized medicine in European countries there has been no reduction in the death rate and that research has practically ceased since there is no longer an incentive.

Mr. A. R. Decker, a journalist of Stony Point, who spent about twenty years in

Europe, pointed out the unsatisfactory workings of the practice of medicine controlled by the State. Under the insurance plan, as carried out in many countries of Europe, the government selects the physician for the patient. In speaking of conditions in this country, Mr. Decker felt that the indigent cases should be cared for but, in his opinion, the physician should not be taxed twice; he pays his taxes as other citizens in hospitalizing such cases, but he should not be asked to give his services free in treating them.

Dr. George A. Leitner who recently attended the annual meeting of the American Medical Association, as a delegate from the Medical Society of the State of New York, held at Cleveland, Ohio, from June 11th to 15th, introduced a resolution which was unanimously passed by the Medical Society of the County of Rockland, declaring in favor of the ten-point declaration policy of the American Medical Association for guidance of physicians and the public in considering any changes in the practice of medicine.

The following resolution was presented and passed: that "the Medical Society of the County of Rockland pay from the funds of its treasury the sum of \$150.00 to the Treasurer of the Bureau of Compensation-Arbitration, consisting of the counties of Ulster, Dutchess, Putnam, Orange, and Rockland, to defray the expenses for one year's operation."

BOOKS REVIEWED

The Single Woman.—A Medical Study in Sex Education. By Robert Latou Dickinson and Lura Beam. Octavo of 469 pages. Baltimore, Williams & Wilkins Company, 1934. Cloth, \$5.00. (Medical Aspects of Human Fertility Series, issued by the National Committee on Maternal Health, Inc.)

More of Dickinson's marvelous case records—1,078 histories of single women are considered—an expedition into a territory almost unknown. The authors' interest is in the sexual as it should influence health and treatment. In the first chapter woman is shown us in the perspective of the nineties when her organs "served apprenticeship to modesty until they reached biological ends."

Sociologically, psychologically, medically—although the authors say that in the strictest sense it is not medical—the book is interesting and instructive. The gynecologist will appreciate it. We may not all agree as to the value of this book, but that there are a great many lessons to be learned from it no one can deny. Dickinson's case records should be a source of inspiration to every

serious gynecologist. They are more than interesting.
CHARLES A. GORDON.

The Modern Treatment of Syphilis.—By Joseph Earle Moore, M.D. Octavo of 535 pages. Springfield, Ill., Charles C. Thomas [c. 1933]. Cloth, \$5.00.

This book is a storehouse of information concerning all phases of the therapy of syphilis. The text is clear, concise and very readable and is intended for all clinicians who have to do with the treatment of the dread disease. The experience of the author together with that of his confreres is based upon a twenty-year out-patient venereal service at the Johns Hopkins Hospital.

The statistical tables throughout the work are a valuable adjunct to the text. As the author states, "the physician must have a basic knowledge of the biology, clinical course, and pathology of syphilitic infection." "Complex situations often arise and the treatment of the disease becomes an art which only those

LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

Death by Accident or Disease?

A case recently decided by the highest court in this State will illustrate the perplexing problems of a medical nature which frequently are the source of litigation. In that case the question at issue was whether in legal contemplation a certain man died by reason of accidental injuries or by reason of disease.

A certain M., almost 70 years of age, carried a policy of accident insurance whereby the company agreed to pay a certain sum to his wife in case he should die as the result of bodily injuries accidentally sustained "directly and independently of all other causes." The insured was a man of very active and energetic nature and to all outward appearances he was in excellent health. In the course of his work, while driving his automobile along a country road at night, he crashed into the rear of an unlighted motor truck which was parked on the highway. The impact was a heavy one causing the heavy truck to be pushed some 20 feet and demolishing the smaller car. In the collision M. struck his chest against the steering wheel of his car. He was found lying on the roadside bleeding from his nose and mouth and complaining of great pain and agony. He was taken directly to a hospital and made particular complaint of pains in the chest and groaned with pain as he breathed. Morphine was administered to him to relieve the pain and the superficial wounds were closed. X-rays were taken the same night which showed the result of a violent blow upon his chest, to be separation of the third right and left costal cartilages. The doctor who attended him found that he was suffering from a moderate degree of shock. M. remained a patient at the hospital, the pain gradually cleared up and after five or six days his breathing was fairly normal, causing him little pain. The lacerations that he sustained substantially healed. There were no other evidences of any injuries.

The patient, however, never left his bed in the hospital and died about three weeks after the accident. During the last ten days he was somewhat irrational and for about

three days prior to his death he was in a state of coma most of the time. One of the doctors who attended him described the conditions leading up to his death as follows:

"As a result of the injury to his chest there was a resultant shock. Very soon after this shock was present there were increasing evidences of trouble in his intestinal tract and with his urinal tract. The poisons which were absorbed as a result of this failure of elimination produced the poisons in his system, the blood absorbing them and carrying them to all parts of his body. As a result of this poisoning all of the organs in the body, of course, were more or less weakened, their function was lessened and resulted ultimately in his death."

The company with whom M. was insured refused to consider his death the result of bodily injuries accidentally sustained independently of other causes and a suit was brought to enforce payment of the amount of the accident policy. It was brought out upon the trial that the immediate cause of the death was nephritis. The death certificate had given the preliminary cause of death as nephrosclerosis, arterial type. It was shown that M. had been suffering from chronic and progressive nephritis for at least three years. An autopsy which had been performed showed that M. had suffered from chronic appendicitis, chronic inflammation of the prostate, that the left coronary artery was thickened, narrowed and calcified indicating hardening of the arteries, and that there were certain adhesions about the intestines, all in addition to the condition of nephritis. The doctors who testified upon the trial stated that all of these conditions which had existed prior to the accident, had, coupled with the accident, caused death. The medical testimony in the case made it clear that, except for the accident, none of the conditions from which the deceased suffered would have been likely to have caused his death in a short period of time, and that he might have lived on for some years.

At close of plaintiff's testimony the complaint was dismissed by the trial judge upon the grounds that the proof showed that death had not been caused solely through accidental means. The plaintiff

appealed to the Appellate Division and that court adopted the view that the plaintiff was entitled to recover on the accidental policy for the reason that the deceased's ailments would not have produced death at the time of the accident nor probably for years, except for the shock which the deceased suffered as a result of the collision. The insurance company, however, carried the case to the highest court of this State and the said court by a four-to-two decision reinstated the ruling of the trial court.

The Court of Appeals decided that under a policy of insurance phrased in such terms as the one in question had been, "the insurer may be relieved of liability if an idiosyncratic condition of mind or body predisposing the insured to injury is so acute as to constitute a disease."

The court stated the rule which permits an insurance company to avoid liability on an accident policy where diseases contribute to the cause of death as follows:

"The disease or the infirmity must be so considerable or significant that it would be characterized as disease or infirmity in the common speech of men . . . of such quality or degree that in its natural and probable development it may be expected to be a source of mischief."

In deciding that the plaintiff had failed to establish her case against the insurance company the court said:

"The burden was on plaintiff to show that the idiosyncratic condition of M.'s body, upon which the accidental injury impinged ultimately to cause death, was not a disease within the meaning of the established rule. The burden was not met. Nephritis existent for at least three years, chronic and progressive, may not with any fitness of language or with any sense of reality be described as a mere predisposing tendency. It is a condition which in its natural and probable development may be expected to be a source of mischief, and so a disease; and if it were mentioned as inflammation of the kidneys instead of nephritis, the ordinary man in his common speech would unquestionably call it a disease."

Clearly the problem before the court was difficult of solution and it may seem that the result reached was a harsh one. However, the decision was probably the only proper one under the circumstances for if the line were not drawn, it can readily be seen that there would be no limit to the abuses which would follow an accident in every case where a person carrying an accident policy suffered death, regardless of the actual cause of that death.

Death of Infant Following Delivery

A woman about 26 years of age came to the office of Dr. B. and informed him that she was pregnant and desired to be confined. Upon examination it was disclosed that she was about six months pregnant and normal. The doctor saw her several times thereafter, and finally one night about three months later she called at his office at 11 P.M. and stated that she was in labor.

The doctor ordered her into a hospital and upon examining her failed to find the fetal heart and advised immediate delivery. Under a general anesthesia a female child was delivered with low forceps. The child was not breathing and was cyanotic. Artificial respiration was given using oxygen and applied warmth. The placenta was expelled intact normally. The child was revived sufficiently to breathe, but she could not retain nourishment. A pediatric specialist was called, but the child died two hours later.

An action for malpractice was brought against Dr. B., and after extensive negotiations with the attorney for the patient, and as the case was about to go to trial, the suit was dropped, thereby exonerating the doctor from the charge of malpractice.

BOOKS REVIEWED

(Continued from page 743)

with wide experience should attempt to practice." The work of Moore may be aptly called a clinical encyclopedia and is, in the reviewer's opinion, the most valuable contribution in English on this subject since the work of Stokes.

AUGUSTUS HARRIS

Bergey's Manual of Determinative Bacteriology.—By David H. Bergey, Fourth Edition. Octavo of 664 pages. Baltimore, The Williams & Wilkins Company, 1934. Cloth, \$6.00.

This is a new edition of the volume absolutely essential to the bacteriologist in any field. It is the ultimate standard for classification and is the only modern reference of its scope for identification. There have been added since the last edition (1930), fifty new species and one new genus, together with new descriptions and amplifications covering three genera and one order. The efficient working arrangement of

material and the clearly concentrated tabulations of data are practically faultless.

IRVING M. DERBY

Industrial Health Service.—By Leverett D. Bristol, M.D. 12mo. of 170 pp. Phila., Lea & Febiger, 1933. Cloth, \$2.00.

The author of this book shows very definitely that he is well versed in the art of industrial medicine. He has covered the entire field in a very clear and comprehensive effort to portray the problems and the solutions that beset both employer and employee from a health standpoint.

This book should be a guide for physicians in industry and should be particularly enlightening to those executives who are interested in the maintenance of employee health.

J. J. WITTMER

ON THE RELATIONS OF THE INCRETA OF THE ADENOHYPOPHYSIS
TO THE CLINICAL DISTURBANCES OF GROWTH, OF DEVELOPMENT, AND OF OTHER PHYSIOLOGICAL FUNCTIONSLEWELLYS F. BARKER, M.D.
Baltimore, Md.

Though P. Marie, in 1886—less than 50 years ago—in his studies of acromegaly was, perhaps, the first to demonstrate the basis of a human disease in pathological changes in the hypophysis cerebri, it was not until after the opening of the new century that rapid progress began to be made toward a better understanding of the pituitary gland and its disorders. Babinski, in 1900, and Fröhlich, in 1901, reported cases of the type now designated dystrophia adiposogenitalis. Cushing and his associates in Halsted's clinic in Baltimore, by their vigorous clinical and experimental work gave a great impetus to hypophyseal investigation in the second half of the first decade of the century; their findings were summarized by Cushing in his *Harvey Lecture* (1910) and in the volume, entitled "The Pituitary Body and Its Disorders" (1912) and included reports on the first experimental production of the adiposogenital syndrome in animals and on the disturbances of carbohydrate metabolism that may be met with in hypophyseal diseases.

ADENOHYPOPHYSIS AND NEUROHYPOPHYSIS

Anatomical and histological studies have revealed marked differences in the structure of the hypophysis in different animals and have shown its intimate relations to the hypothalamic region of the interbrain. The glandular part of the hypophysis as a whole is now spoken of as the adenohypophysis, whereas the posterior lobe is called the neurohypophysis. In the adenohypophysis of the nonpregnant adult human female, the chief cells forming about 50 per cent of all the cells are chromophobe; the other cells are chromo-

phile cells, the eosinophiles forming about 43 to 44 per cent and the basophiles about 7 per cent of the total number of cells; in males the proportion of eosinophiles is slightly less than in females (A. T. Rasmussen, 1933).

INCRETA FOUND IN THE ADENOHYPOPHYSIS

Many chemical substances, apparently of hormonal nature, appear to be produced by the cells of the adenohypophysis. I shall mention only those concerning which we have data that support their significance.

1. THE GROWTH HORMONE.—This substance, shown by Evans and Long (1921) to be present in alkaline aqueous extracts of the adenohypophysis is necessary for the growth of young animals. In its absence, growth ceases. Administered in excess to a young rat or to a young pure-bred dachshund, it will give rise to gigantism. It is not excreted in the urine. There seems to be no doubt that it is a product of the eosinophile cells of the adenohypophysis. Recently (1933) Collip has obtained it in concentrated form ("Q extract") by concentrating bovine extracts of the anterior pituitary; in this form it is said to be absolutely free from the gonadotropic hormone, the thyrotropic hormone, and the adrenotropic hormone of the adenohypophysis. In animals treated with it, nitrogen excretion is quickly and markedly decreased; it appears to affect protein metabolism as much as it does calcium metabolism.

2. THE GONADOTROPIC OR MATURITY HORMONE.—As early as 1901 clinicians reported atrophy of the sex organs in certain patients with disease of the hypophysis

and in 1926 it was shown by experimental studies that implantation of anterior pituitary under the skin of young rats would quickly give rise to sexual maturity (Zondek and Aschheim; P. E. Smith); the effects in immature females were similar to the effects produced by the substances known as prolans and present in the urine of pregnant women, but the gonad-stimulating hormone of the hypophysis is not identical with prolans. This maturity hormone of the anterior pituitary is believed to be a product of the basophile cells (J. H. Biggart, 1933; E. J. Kraus, 1933).

3. THE THYREOTROPIC HORMONE.—In experimental animals, it was shown that removal of the hypophysis caused atrophy of the thyroid (B. Allan and P. E. Smith, 1915.) Clinical studies proved the existence of a low basal metabolic rate and of low specific dynamic action of protein in destructive diseases of the adenohypophysis. Convincing evidence of the existence of a thyreotropic hormone in the adenohypophysis was, however, first brought by L. Loeb (1931-1932) in this country and by M. Aron in Germany; it has recently been obtained in relatively purer form by Collip (1933). It is not identical with the adrenotropic hormone nor with the growth hormone, but seems to have a specific effect upon the thyroid gland itself. Its chemical properties have been studied by Krogh and Okkels (1933). It is not known yet which cells of the adenohypophysis produce it. Injections of this hormone will cause hyperplasia of the thyroid of a hypophysectomized rat in about a week and will restore the thyroid activity to normal in $2\frac{1}{2}$ months though the maximal effect is exerted in one or two weeks.

4. THE ADRENOTROPIC OR INTERRENOTROPIC HORMONE.—That the adenohypophysis produces a hormone that is essential for the welfare of the suprarenal cortex is shown by the fact that after experimental removal of the pituitary gland marked atrophy of the cortex occurs. Many of the animals sicken and die and Evans found that administration of Swingle's adrenal cortical hormone would not modify the decline, though he obtained dramatic improvement on administration of aqueous alkaline extract of the anterior pituitary, results that make him hopeful that if a more concentrated extract containing this "interrenotropic hormone" can

be obtained it may prove to be useful in the treatment of Addison's disease. The marked hyperinterrenalism that is seen in Cushing's syndrome (basophile adenoma of the pituitary) may possibly be due in part to overproduction by the adenohypophysis of this interrenotropic hormone in which event we might think of the basophile cells as the producer of the hormone.

5. THE HORMONE INFLUENCING FAT METABOLISM.—Evidence of the existence of such a hormone is seen (1) in the observation that lack of it is followed by obesity (some deny this) and lowering of the basal metabolic rate, and (2) in the fact that excess of it leads to increased formation of beta-oxybutyric acid (Anselmino and Hoffman, 1931). The hormone is said to be water-soluble and protein-free. It can be separated from the maturity hormone, the growth hormone, the lactogenic hormone and the thyreotropic hormone by ultrafiltration; it is present in the blood apparently only when fat is being burned.

6. THE HORMONE INFLUENCING CARBOHYDRATE METABOLISM (DIABETOGENIC HORMONE).—Cushing observed increased carbohydrate tolerance after ablation of the pituitary body. Later it was shown that hypophysectomized dogs exhibit an increased sensitivity to insulin (Houssay-Magenta, 1924) and that experimental pancreatic diabetes can be ameliorated by removal of the pituitary body, though if anterior lobe be then implanted, hyperglycaemia immediately recurs. Evans and his associates (1932) produced saccharine diabetes in normal dogs by giving them alkaline extracts of the hypophysis; these findings suggest that the diabetogenic hormone of the hypophysis is pancreatropic and may repress the functions of the islands of Langerhans of the pancreas.

7. THE LACTOGENIC HORMONE.—That the adenohypophysis produces a hormone (so-called "prolactin") that regulates the secretion of milk now seems to be certain. Though the hormone from the corpus luteum may be of importance for mammary development the studies of Corner, and more recently of Riddle, indicate that after the mammary glands have undergone development, the lactogenic hormone of the hypophysis is necessary for the stimulation of the secretion of true milk.

8. OTHER HORMONES PRODUCED BY THE ADENOHYPHYSIS.—Though the hormones already mentioned appear to be those of greatest importance, it is probable that the adenohypophysis is instrumental in the production of still others. Thus, it has been shown that extracts of human hypophysis given to frogs will darken their color by causing a spreading out of the melanophores of the skin (Ehrhardt) and that extracts of the pars tuberalis of the cat's hypophysis contain both a diuretic substance (Teel) and an antidiuretic substance (Atwell). Whether the hormones that are extractable from the posterior lobe and stalk (tonephin and oxytocin and the antidiuretic substance in pituitrin) are manufactured by glandular cells that have wandered from the adenohypophysis into the neurohypophysis is still under dispute; certainly these substances do not seem to be present in extracts of the anterior lobe. The intermedin present in large amounts in the pars intermedia of the bovine hypophysis (Zondek and Krohn) and which gives a red color to the skin of certain animals ("wedding dress") has been found to be present in the human adenohypophysis and may be very abundant as Berblinger has shown, in conditions in which the basophile cells are increased (*e.g.*, in eunuchoid obesity, cancer of the liver, and uremia). This "intermedin" is not identical with the melanophore-spreading substance previously mentioned.

THE RELATION OF DISTURBANCES OF PRODUCTION OF THE INCRETA OF THE ADENOHYPHYSIS TO CLINICAL CONDITIONS (OTHER THAN GYNECOLOGICAL)

The writer wishes to emphasize the importance of care in the clinical use of the terms "hyperpituitarism" and "hypopituitarism," since we usually have to deal with conditions that are only partial rather than total hyper- or hypo-states. This is easily understandable now that we know (1) that there are three main types of cells in the adenohypophysis, (2) something of the relations of the increta to these types, and (3) something of the elective involvement of the types in certain diseases. It must be remembered, too, by all who attempt clinical interpretations that injuries to or diseases of the hypophysis cerebri may be accompanied by lesions in the adjacent portions of the diencephalon and that, sometimes, lesions of the latter alone may give

symptoms and signs that closely simulate those of certain hypophyseal diseases. Time will permit only brief mention of the more important pituitary syndromes and of the incretal disturbances probably involved in their production.

1. PITUITARY CACHEXIA (CACHEXIA HYPHYPHYSEOPRIVA).—Since Simmonds (1914) first brought the anatomical proof that destruction of the anterior lobe of the hypophysis can be followed by a progressive and ultimately fatal cachexia, this condition has been called "Simmonds' disease" or "hypophyseal cachexia." More common in women than in men, it has developed most often as a result of embolic necrosis of the hypophysis occurring in the course of puerperal sepsis, though it may follow upon local hypophyseal hemorrhages, inflammations, or neoplasms. The condition is characterized by amenorrhea (in women), impotentia and testicular atrophy (in men), falling out of the hair, decrease in size of the organs (splanchnomikria), hypothermia, premature senility and, ultimately, emaciation with severe anemia. On account of the extensive destruction of the anterior lobe (involving all the chromophobe and chromophile cells) there would seem good reason to assume a deficiency of all the prepituitary hormones in this cachexia. Diabetes insipidus is not a part of the syndrome. In therapy the hypodermic administration of anterior lobe extracts should be tried (J. C. Brougher, 1933).

2. HYPHYPHYSEAL DWARFISM.—A slowly progressive deficiency of the adenohypophysis setting in before puberty gives rise to "pituitary dwarfism" (Erdheim, 1916) or "nanosomia pituitaria." In a clinic held last year, I showed a patient illustrating the condition; good photographs of the patient accompany the report of the clinic in *Endocrinology* (17:647, 1933). Since the growth hormone and the gonadotropic hormone are both deficient it would seem certain that the hormones of the eosinophile and the basophile cells are insufficiently produced, or that they cannot arrive at the sites of their activity (as for example, when a tumor of the craniopharyngeal duct separates the hypophysis from the diencephalon). The patients are not obese, the epiphyseal lines remain open, the bodily proportions remain child-like, and the sex organs and sex life remain underdeveloped, though the intellect may evolve normally.

3. **HYPOPHYSEAL INFANTILISM.**—The peculiar infantilism designated "ateleiosis" by Gilford (1911) was attributed to hypophyseal deficiency by Biedl. It is not to be confused with the faulty growth of hypothyroidism. In this hypophyseal infantilism the "upper length" of the body exceeds the "lower length," the pelvis remains infantile, the subcutaneous adipose tissue does not develop, epiphyseal closure is retarded, the genitalia remain infantile, and, later on, there is a peculiar premature senile appearance (progeria). The condition appears to be due to temporary anterior lobe deficiency occurring at about the time of puberty (H. Lissner). Improvement has followed the hypodermic administration of anterior lobe extracts. Evidently the effects of the increta of both the eosinophile and the basophile cells of the hypophysis are, for one reason or another, insufficient; a delayed ripening of the granular chromophile cells has been suggested as a possible basis.

4. **ACROMIKRIA (DYSTROPHIA OSTEOGENITALIS).**—This condition, first described by T. Brugsch (1927), is characterized by small acra, acrocyanosis, pains in the acra, moderate dwarfism, hypotrichosis, headache, and thirst; in females, there is amenorrhea. In some cases the skull is smaller than normal (probably with microcephaly). No autopsies seem to have been reported. The acromikria is believed to be due to insufficiency of eosinophile cell activity and the genital disturbances to insufficiency of basophile cell activity. The frequent association of polyuria and of obesity with the other symptoms would seem to point to complicating involvement of the nerve nuclei in the hypothalamus.

5. **GIGANTISM AND ACROMEGALY.**—These well-known conditions (one developing before, the other after epiphyseal closure) are now believed to depend upon excessive production of growth hormone by eosinophile cells in the hypophysis. Indeed, at autopsy, eosinophile adenomata are often found, usually in the anterior lobe proper, occasionally in the body of the sphenoid bone; if at autopsy no eosinophile adenoma be found at either of these sites, Berblinger emphasizes the importance of looking for one in the pharyngeal roof in which traces of hypophyseal tissue may remain and be the site of origin of the adenoma. It is to be emphasized, however,

that an increase of eosinophile cells in the hypophysis may occur without evidence of increased production of growth hormone as Wyeth has shown in his histological studies of the hypophysis in cancer. If signs of hypogenitalism accompany gigantism or acromegaly, one may assume the existence of an associated insufficiency of the gonadotropic hormone (perhaps because of pressure of the eosinophile adenoma upon the basophile cells). Occasionally, acromegaly is accompanied by enlargement and hyperfunction of the thyroid gland, a fact that has suggested the possibility that the eosinophile cells of the hypophysis may produce the thyrotropic hormone as well as the growth hormone.

6. **DYSTROPHIA ADIPOSOGENITALIS.**—This syndrome described by Babinski (1900) and more fully by Fröhlich (1901) is relatively common. It is characterized by obesity, genital dystrophy, and (usually) signs of intracranial tumor, though in the so-called Laurence-Biedl syndrome associated with disturbances of intellect and retinitis pigmentosa, there may be no signs of tumor either of the hypophysis or of the brain. Three forms are believed to exist: (1) that due to tumor or other disease of the adenohypophysis alone; (2) that due to interruption of the connections of the hypophysis with the interbrain; and (3) that due to injury of the interbrain alone.

Shortly before his death, W. Engelbach was testing the effects of the growth hormone of Evans upon patients presenting the symptoms of dystrophia adiposogenitalis.

7. **"PITUITARY BASOPHILISM."**—Recently, Cushing has described as "pituitary basophilism" a syndrome characterized by obesity of the trunk (not of the limbs), hypertrichosis, plethoric habitus with erythremia, purple striae on the chest and abdomen, high blood pressure, osteoporosis, kyphosis, and genital disturbances (amenorrhea in the female, impotence in the male). At autopsy, he found hypertrophy of the suprarenal glands and small basophile adenomata in the hypophysis. How much of Cushing's syndrome is due to the basophile adenomata and how much to the hypertrophy of the suprarenal cortex would seem as yet to be uncertain. Zeynek (1933) maintained that basophile hyperplasias of the pituitary are common without symptoms. Further studies of pituitary

basophilism and of Cushing's syndrome will be awaited with interest.

8. DIABETES INSIPIDUS.—In this disorder enormous quantities of urine (even 10 or 20 liters daily) of very low specific gravity are excreted; the kidneys are no longer able, without therapeutic intervention, to excrete a concentrated urine. The fact that injections of extracts of the posterior lobe of the hypophysis (pituitrin) exert a markedly antidiuretic effect in diabetes insipidus (especially if the salt intake be limited at the same time) is well established, but we do not yet know with certainty where this pituitrin is manufactured. Some have thought that cells from the adenohypophysis that have wandered into the posterior neural lobe make it; but extracts of anterior lobe have no effect upon the polyuria and there may be complete destruction of the so-called middle lobe without polyuria. Experimentally, injuries to the medulla oblongata, as well as to the corpora mammillaria or to the hypothalamus may give rise to the same type of polyuria.

Autopsies upon patients who have during life suffered from diabetes insipidus have revealed variable findings—sometimes diseases of the hypophysis (inflammations, tumors), sometimes lesions of the tuber cinereum or of other parts of the diencephalon. The view generally held at present is that some interruption of the correlation of the activities of the hypophysis with those of the interbrain must be responsible for the occurrence of diabetes insipidus, though even this view has been challenged because of observations that such interruptions are not always accompanied by polyuria. The whole matter of the pathogenesis of diabetes insipidus must therefore be regarded as yet undetermined. It is interesting that the disease may sometimes occur in families in a manner suggestive of an inherited anomaly (cf. Chester and Spiegel, 1933).

Symposium on Obstructive Uropathy

OBSTRUCTIONS TO THE UPPER URINARY TRACT

FRANCIS N. KIMBALL, M.D.

From the Department of Urology (James Buchanan Brady Foundation) of New York Hospital and the Department of Urology, New York City Hospital

Urologists of today appreciate the delicate balance with which the urinary system is maintained and realize that if that balance is disturbed, impairment to health results. They are indebted to their colleagues, the physiologists, for knowledge of the functional activity of the kidney. Claude Bernard in his conclusions on the phenomena of life makes the following summation: "All the vital mechanisms, varied as they are have only one objective; that of preserving constant the conditions of life in the internal environment."

The urinary tract as one of those vital mechanisms maintains three important functions: (1) maintenance of the osmotic pressure of the blood at a constant level; (2) excretion of all organic constituents of food which are not required by the body; and (3) excretion of waste products of nitrogenous metabolism, particularly urea and uric acid.

After the urine has been secreted by the tubuloglomerular structure of the kidney it is discharged into the minor calyx. As each calyx fills, contraction occurs and the muscular band at the infundibular portion relaxes to allow the contents to be emptied into the major calyces and the pelvis. Similarly the major calyces and pelvis become filled to a certain degree of distention at which time peristalsis begins, causing the muscular ring at the ureteropelvic junction to relax and allowing the urine to pass into the ureter from which it is discharged into the bladder. In turn the bladder is filled to a certain degree of distention when contraction takes place and the vesical sphincters relax to allow the urine to be voided through the urethra.

Thus the urine passes through five separate conduits: the calyces, pelvis, ureter, bladder, and urethra, a coordinated process, which is accurately controlled by the sympathetic nervous system. Any mechanical change in the pressure within the urinary system will alter the conditions under which the kidney functions and will increase the difficulty on the part of the kid-

ney, in excreting solid substances. Waste products are then retained in the body producing the phenomena of uremia.

ETIOLOGY.—The causes of interference with drainage of the upper urinary tract are many and may be located anywhere from the calyces to the ureterovesical orifice. The actual pathology may be located within the lumen of the drainage canal, or it may be outside of the canal and produce pressure upon it.

The methods of urological diagnosis now at our disposal have demonstrated the frequency with which obstructions are encountered above the bladder and the great variety of anomalies found in the kidney and ureter giving rise to distortions of the urinary conduits.

These causes may be grouped into two general groups which may be called intrinsic and extrinsic, respectively. The intrinsic group includes the following:

1. Pyogenic infections.
2. Tuberculous infections.
3. Inflammation of renal pelvis with blood clot or parasite.
4. Strictures of: calyx; ureteropelvic junction; iliac portion of ureter; midpelvic portion of ureter; ureteral orifice; inflammatory stricture of ureter.
5. Calculus in: calyx causing partial hydronephrosis; pelvis; ureter.
6. Tumors of: kidney; pelvis; ureter; ureteral orifice.
7. Anomalies of: kidney; pelvis; ureter.

The extrinsic group includes the following:

1. Aneurysm of renal artery.
2. Aberrant vessel or fibrous band at ureteropelvic junction.
3. Adhesions: about ureter causing a kink in nephroptosis; resulting from abdominal or pelvic inflammatory disease; resulting from seminal vesiculitis; cicatricial stricture inflammatory or postoperative.
4. Tumors producing pressure on ure-

ter: abdominal; pelvic; pregnancy; diverticulum of bladder; calcified lymph nodes.

PATHOLOGICAL PHYSIOLOGY.—The results of obstruction upon the kidney are practically the same regardless of the place at which the obstruction occurs. The anatomic and functional changes will vary in their relative importance, depending upon the distance that the obstruction is located from the kidney. In upper-tract obstructions the pressure effects come on more acutely and the anatomic changes make their appearance at once. The functional impairment is so slight that it usually causes no immediate symptoms.

Obstructions may be partial or complete and in either case may be constant or intermittent. This results in a progressive hydronephrosis with its ultimate effects, hydronephrotic atrophy.

Hinman and his associates have shown that hydronephrotic atrophy is a type of the degeneration produced by pressure and anemia; that there is a direct relationship of urinary back pressure to the blood supply, the productive factor in dilatation and atrophy. In a closed hydronephrosis, the contents are neither cumulative nor stagnant. The change is continuous. Urine is being secreted by the kidney and the excess is removed by an active reabsorption which occurs through pyelovenous backflow.

Some of the mechanical effect may be better understood if we consider the blood supply to the kidney. The renal artery divides as it reaches the hilum into several branches varying in numbers from three to five entering the kidney substance independently. These branches partially surround the renal pelvis. The progressive dilatation of the pelvis will compress and gradually strangle the arterial supply. In a similar manner there is a dilatation of the calyces and ultimately the collecting tubules. Pressure is exerted upon the peritubular capillary plexus and it is deprived of its blood supply. These capillaries deprived of their blood supply degenerate first, the less injured with some blood supply are able to maintain some degree of secretion; thus the atrophy progresses.

As the pelvic dilatation progresses the calyces which are in direct communication with the pelvis are subjected to the same pressure, become widened and the papillae flattened until their orifices are marked by slight central elevations, with radiating

blood vessels and tubular markings. The pyramids lose their radial appearance as the tubules are forced to lie upon the surface beneath and parallel with the capsule. The cortex becomes very thin and in due time the unequal blood supply produces areas of different thickness giving an irregular appearance to the gross kidney. The process may continue until the whole kidney is reduced to a multilocular sac with patches of thin or thick renal cortex distributed in an otherwise thin wall of sac. The remaining cortex will show areas of focal fibrosis with infiltration of lymphocytes and plasma cells. The glomeruli will vary in size, some may be converted into fibrous nodules, others surrounded by a thickened fibrous capsule. Renal tissue is reduced to such a small amount that restitution of function is impossible.

The intrarenal and extrarenal pelves produce differences in the gross appearance of a hydronephrotic kidney. In the former the pelvis is partially surrounded by the more resistant renal tissue so that in extreme dilatation there is a radial enlargement with the remaining renal tissue spread out over the surface of the sac. In the latter there is a less resistance offered so that the pelvis dilates in extreme cases to a large sac with a small amount of renal tissue in one area of the periphery.

The degree of functional impairment will vary in different cases to the degree of hydronephrosis present. We have seen a kidney with a considerably dilated pelvis show a normal function. This condition will be found in a hydronephrosis which is characterized by recurrent attacks of pain and swelling with intermissions which tend to preserve the renal function. An obstruction which is progressive will show functional impairment before marked dilatation is evident. A hydronephrosis of a week to ten days' duration resulting in a purely functional disturbance undergoes complete restitution to normal when the obstruction is removed provided no permanent structural change in the kidney has occurred. On the other hand, a hydronephrosis of much longer duration requires the stimulus of compulsory function, which must be gradually applied. Renal tissue is stimulated to greater activity resulting in renal hypertrophy, when there is a gradual increasing demand for more work—a physiological principle which is well known to all of us: activity is essential to development and inactivity encourages atrophy.

Symposium on Obstructive Uropathy

OBSTRUCTIONS TO THE UPPER URINARY TRACT

FRANCIS N. KIMBALL, M.D.

From the Department of Urology (James Buchanan Brady Foundation) of New York Hospital and the Department of Urology, New York City Hospital

Urologists of today appreciate the delicate balance with which the urinary system is maintained and realize that if that balance is disturbed, impairment to health results. They are indebted to their colleagues, the physiologists, for knowledge of the functional activity of the kidney. Claude Bernard in his conclusions on the phenomena of life makes the following statement: "All the vital mechanisms, varied as they are have only one objective; that of preserving constant the conditions of life in the internal environment."

The urinary tract as one of those vital mechanisms maintains three important functions: (1) maintenance of the osmotic pressure of the blood at a constant level; (2) excretion of all organic constituents of food which are not required by the body; and (3) excretion of waste products of nitrogenous metabolism, particularly urea and uric acid.

After the urine has been secreted by the buloglomerular structure of the kidney is discharged into the minor calyx. As each calyx fills, contraction occurs and the muscular band at the infundibular portion relaxes to allow the contents to be emptied to the major calyces and the pelvis. Similarly the major calyces and pelvis become filled to a certain degree of distension at which time peristalsis begins, causing the muscular ring at the ureteropelvic junction to relax and allowing the urine to pass into the ureter from which it is discharged into the bladder. In turn the bladder is filled to a certain degree of distension when contraction takes place and the vesical sphincters relax to allow the urine to be voided through the urethra.

Thus the urine passes through five separate conduits: the calyces, pelvis, ureter, bladder, and urethra, a coordinated process, which is accurately controlled by the sympathetic nervous system. Any mechanical change in the pressure within the urinary system will alter the conditions under which the kidney functions and will increase the difficulty on the part of the kidney,

in excreting solid substances. Waste products are then retained in the body producing the phenomena of uremia.

ETIOLOGY.—The causes of interference with drainage of the upper urinary tract are many and may be located anywhere from the calyces to the ureterovesical orifice. The actual pathology may be located within the lumen of the drainage canal, or it may be outside of the canal and produce pressure upon it.

The methods of urological diagnosis now at our disposal have demonstrated the frequency with which obstructions are encountered above the bladder and the great variety of anomalies found in the kidney and ureter giving rise to distortions of the urinary conduits.

These causes may be grouped into two general groups which may be called intrinsic and extrinsic, respectively. The intrinsic group includes the following:

1. Pyogenic infections.
2. Tuberculous infections.
3. Inflammation of renal pelvis with blood clot or parasite.
4. Strictures of: calyx; ureteropelvic junction; iliac portion of ureter; midpelvic portion of ureter; ureteral orifice; inflammatory stricture of ureter.
5. Calculus in: calyx causing partial hydronephrosis; pelvis; ureter.
6. Tumors of: kidney; pelvis; ureter; ureteral orifice.
7. Anomalies of: kidney; pelvis; ureter.

The extrinsic group includes the following:

1. Aneurysm of renal artery.
2. Aberrant vessel or fibrous band at ureteropelvic junction.
3. Adhesions: about ureter causing a kink in nephroptosis; resulting from abdominal or pelvic inflammatory disease; resulting from seminal vesiculitis; cicatricial stricture inflammatory or postoperative.
4. Tumors producing pressure on ure-

arrested. A small stone may wander about the pelvis to rest in its most dependent portion, or it may become impacted in the neck of a calyx or the ureteropelvic junction. If impacted in the calyx, it may grow to an enormous size causing marked destruction of the kidney before obstruction occurs. When arrested in the pelvis, a partial or incomplete hydronephrosis may result which, as mentioned before, may become very large. Should the obstruction be complete and sudden, the resulting hydronephrosis will be smaller. We must remember that stone in the kidney is a destructive process which is greatly augmented by infection; therefore every effort should be made to conserve the function of renal tissue.

Ureteral stone may be arrested either temporarily or permanently at one of the normal constricted areas of the ureter, namely; opposite the iliac artery, mid-pelvic portion or in the intramural portion. If arrested in any of these areas the stone will continue to grow and in addition to the hydronephrosis there is a hydro-ureter. Infection will produce scarring with contracture and finally stricture formation which will interfere with the restitution of normal function.

Tumors of the renal pelvis and ureter may be short and spreading or tall and pedunculated. They may be classified as benign or malignant; however, they are potentially malignant and are usually identical with those found later in the bladder. Those of the pelvis sooner or later extend into the ureter, or implants are worked down with the stream of urine to lodge in one of the areas of constriction. Primary tumors or implants in the ureter grow until they produce a partial or complete obstruction. Often, due to the interference with drainage, calculi develop.

In practically all of the anomalies of the kidney and ureter drainage is very poor. This favors infection and calculus formation. Obstruction occurs with its resultant hydronephrosis and pyelonephrosis.

The extrinsic causes of upper urinary tract obstructions are indirect in their casual relationship and can produce some very perplexing problems. They are mechanical in nature and produce their effect by pressure upon some part of the urinary tract. An aneurysm of the renal vessels while rare can exert such pressure on the pelvis that complete obstruction

occurs. Aberrant vessels or fibrous bands about the ureteropelvic junction cause a partial obstruction resulting in very large hydronephrosis. Adhesions, inflammatory or postoperative in area near the course of the ureter, can and do cause constriction of the ureter. Pelvic adnexal diseases in the female, and seminal vesiculitis in the male very often are causes that are overlooked. Tumors, both pelvic and abdominal, may cause marked distortions of the ureter. Recently the author observed a very interesting case in which there was pressure exerted upon the ureter by a calcified lymph node.

In searching for the causes of obstruction of the upper urinary tract we must be on the alert and remember that we may find the cause either intra-urinary or extra-urinary at any point along the urinary tract from a calyx to the uterovesical orifice.

CLINICAL RECOGNITION.—The diagnosis of obstructions of the upper urinary tract is based upon painstaking clinical history, general examination, and complete urological examination. Obstruction of the upper urinary tract may be bilateral but usually is unilateral, and the symptoms are local. Anatomic changes take place early, before renal functional disturbances are present. The symptoms of the early anatomic changes are the first to be brought to the attention of the patient and his doctor. Herein lies one of the points of differentiation between upper and lower tract obstructions. In unilateral upper tract obstructions the symptoms are local, while in the lower tract the symptoms are general with marked disturbance of renal function, which causes the patient to be ill before anatomic changes take place.

The *signs and symptoms* in the order of their importance are as follows: pain, hematuria, pyuria, tumor, urgency, frequency, and polyuria. Pain which is the most characteristic symptom is usually colicky and recurrent in type. It varies with the nature and site of the obstruction, usually located in the costovertebral angle or loin and radiating down the course of the ureter. Nausea and sometimes vomiting accompany the pain. Hematuria may be present with all types of obstruction, most common with calculi and very often with ureteral strictures and renal infections. This may be explained by the fact that beneath the mucosal coat in such cases there is an ecchymosis which in all

probability is related to the intrapelvic pressure. Pyuria is always present in some degree in calculus. When infection is present, the picture may become altered by chills, fever, prostration, severe pains, and marked tenderness which is limited to the loin and costovertebral angle.

Palpable tumor is a very inconstant sign, and often in a fat individual a large hydronephrosis may not be palpated. On the other hand, in a thin individual an intermittent hydronephrosis may be palpated as a tumor before any other symptoms are present. As this type of hydronephrosis empties itself, the patient may complain of urgency, frequency, and polyuria.

The examination of the urinary tract should be done in a thorough and systematic manner. A careful complete cystoscopic examination must be done. In those cases which cannot be cystoscoped one can resort to intravenous urography which, while it does not give all the information desired, is a valuable adjunct and should be used. By the use of ureteral catheterization one can obtain important information by thorough chemical, microscopic, and bacteriologic study of the urine specimens obtained from each kidney.

The functional activity of each kidney is very important and should be determined before any treatment is begun. There are several methods. One should be chosen which can be done without great difficulty; among these methods may be mentioned the indigo-carmin and the phenolsulphonaphthalein tests. The latter is favored because it is simple and can be estimated with some degree of accuracy. When the dye is given intravenously to a normal individual the healthy kidney will secrete one per cent per minute for the first half hour. Therefore we determine the time required for its appearance, then collect specimens from both sides for a period of ten minutes after its first appearance regardless of the side in which it first appears. Also, we know that a diseased kidney secretes a more dilute urine than a healthy one, therefore the urea secreted by a healthy kidney will be more concentrated than its diseased fellow. This may be quickly and accurately determined by the hypobromide test. This test and the phthalein test will give us much information regarding the functional activity of each kidney. Our examination is never complete without radiography. This can

be done very quickly at the same time as cystoscopy, after specimens have been collected. With the various types of urological tables now at our disposal, we need not move our patient during the entire procedure. Plain radiography will greatly aid in determining the size, shape, and position of the kidney; also the site and degree of obstruction. This is particularly true in 85 to 90 per cent of the cases of hydronephrosis and renal calculi. Information is obtained as to the size, location, fixation, or mobility of the calculus, whether in the ureter, pelvis, or calyces, whether the pelvis is normally developed or abnormal. Often the question arises as to whether the shadow seen in plain radiography is intra- or extra-urinary. This point is often clarified by double exposure of the same plate by shifting the plate a few centimeters between exposures. If the shadow is intra-urinary it will be in contact with the radiograph on both exposures.

Pyelography and ureteropyelography are very important and if done with care and precision are painless. With the various preparations at our disposal the author never hesitates to do bilateral pyelograms if such are indicated; it saves time and expense and gives great aid in the completeness of the examination.

Their interpretation requires a trained eye and experience is the best teacher. The urologist who does the cystoscopy has the greatest advantage because he is able to use the clinical knowledge gained during the cystoscopic examination. From the procedure the urologist can determine the location of the obstruction, whether it is intra- or extra-renal or in a calyx that does not communicate with the renal pelvis. With the various filling defects and bizarre distortion to the pyelo-ureterogram he is able to determine whether a neoplasm is in the renal pelvis, parenchyma, or outside the urinary tract. Of great importance is the additional information obtained with reference to the damage sustained by the kidney.

TREATMENT.—The problem of treatment of obstructions of the upper urinary tract is similar to the treatment of other illnesses—to restore the affected part to as near the normal as possible. To reach this objective a most careful and well-supervised medical, preoperative, operative, and sometimes prolonged post-operative treatment is required.

After a careful examination we know the extent of the damage done and the functional capacity of each kidney. This will determine the type of treatment to be undertaken—nonoperative or operative. First, we must establish the proper permanent drainage to permit the restoration of function. If the obstruction has not been removed during this procedure, it can more safely be accomplished later.

Obstructions due to infections, ureteral strictures, and small calculi are preferably treated by nonoperative treatment. To accomplish this end we have the following methods available: urinary antiseptics, diet and drugs to change the reaction of the urine, inlying ureteral catheters, ureteral dilatations, renal pelvic lavage, and the elimination of foci of infection in other parts of the body.

While we are still in search of a satisfactory urinary antiseptic, we can utilize those available, with a marked degree of success. They should be used in all cases of infections of the urinary tract. Helmholtz and Clark have obtained excellent results with the use of diet and drugs. Their theory briefly stated is as follows: "The organism causing the infection must be known from the start. The hydrogen ion concentration must be determined and recorded when the patient first comes under observation. Diet and drugs are used to the extent necessary to increase the hydrogen ion concentration to the neighborhood of 5.0 and this level of acidity is maintained if possible until the urine is known to be sterile."

The use of an inlying ureteral catheter is often a life-saving procedure in acute cases. It should remain in place until adequate drainage is obtained and the acute stage subsides. With the control of the infection normal drainage is reestablished. The catheter should be irrigated at intervals of three to four hours with one of the many bland urinary antiseptic solutions of proper dilution.

Ureteral dilatations using bougies varying in size from a filiform to those of a 10 to 12 F. caliber give excellent results in the treatment of stricture and small calculi. Dilatations of the ureter with lavage of the renal pelvis should be repeated at intervals varying from ten to fourteen days until the obstruction and infection have been removed. Dilatation has a particular appeal in cases of small bilateral and recurrent calculi; also, in patients who

are not good operative risks the ureter may be dilated sufficiently to facilitate the passage of the stone. There are definite and serious dangers associated with cystoscopic manipulative treatment. Unsuccessful instrumentation may result in injury to the ureter such as rupture, or may be followed by infection. The rapid progress of the infection will be favored when the obstruction has not been removed. It is desirable to have the patient under close observation at all times, so that proper measures may be undertaken as soon as indicated.

The operative treatment depends upon many factors such as, the location, size, shape, multiplicity, character, and the destructive changes in the kidney, resulting from the obstruction. Of most importance is the condition of the patient and the condition of each kidney. The operative procedure chosen should be that which conserves the most renal tissue. In the removal of calculus obstruction, pyelotomy is preferable to nephrotomy. In either case the kidney should be drained for a period of four to five days by means of a small catheter placed in the most dependent portion of the pelvis. The pelvis may be irrigated at intervals of from three to four hours.

In severe renal destruction with pain, infection, and toxemia, nephrostomy is the immediate treatment of choice, to be followed later by nephrotomy or nephrectomy.

The treatment of bilateral obstructions presents some perplexing problems. We have adopted a policy of removing the obstruction from the kidney with the better function first. In such cases we can safely rely on the good kidney to carry the patient through the convalescence of the second operation if nephrectomy should be required.

In unilateral obstructions resulting from tuberculosis infections and neoplasms, nephrectomy with as much removal of ureter as possible offers the best results. All neoplasms of the renal pelvis and ureter should be considered as potentially malignant and should be treated by complete nephro-ureterectomy, including a cuff of the bladder surrounding the ureteral orifice.

In all cases of upper tract obstructions regardless of the cause the patient should be observed at intervals of sufficient frequency to control the recurrence of the obstruction.

probability is related to the intrapelvic pressure. Pyuria is always present in some degree in calculus. When infection is present, the picture may become altered by chills, fever, prostration, severe pains, and marked tenderness which is limited to the loin and costovertebral angle.

Palpable tumor is a very inconstant sign, and often in a fat individual a large hydronephrosis may not be palpated. On the other hand, in a thin individual an intermittent hydronephrosis may be palpated as a tumor before any other symptoms are present. As this type of hydronephrosis empties itself, the patient may complain of urgency, frequency, and polyuria.

The examination of the urinary tract should be done in a thorough and systematic manner. A careful complete cystoscopic examination must be done. In those cases which cannot be cystoscoped one can resort to intravenous urography which, while it does not give all the information desired, is a valuable adjunct and should be used. By the use of ureteral catheterization one can obtain important information by thorough chemical, microscopic, and bacteriologic study of the urine specimens obtained from each kidney.

The functional activity of each kidney is very important and should be determined before any treatment is begun. There are several methods. One should be chosen which can be done with-

out; among these, the *intravenous urography* can keep at their finger tips all of the latest diagnostic features, and hence too often they let a patient drift into a condition which spells extreme effort to ameliorate, with a long convalescence and perhaps a question as to the ultimate recovery hanging in the balance.

To wit: The prostatic conditions which are allowed to run on for months with dependence only on favorite or widely advertised urinary antiseptics, and not collecting chronologically enough chemical data to warrant judgment as to the patient's improvement—while valuable time is lost and the condition is progressing to other organs, until both the genital and urinary tracts may be completely affected.

2. Stop some of the apparent haphazard surgery in the urological field, especially in bladder conditions which seems to be in the making by some who are skilled in mechanical surgery, but are lacking in tech-

be done very quickly at the same time as cystoscopy, after specimens have been collected. With the various types of urological tables now at our disposal, we need not move our patient during the entire procedure. Plain radiography will greatly aid in determining the size, shape, and position of the kidney; also the site and type of obstruction. This is particularly true in 85 to 90 per cent of the cases of ureteral and renal calculi. Information is obtained as to the size, location, fixation, or mobility of the calculus, whether it is in the ureter, pelvis, or calyces, whether it is in a normally developed or abnormal kidney. Often the question arises as to whether the shadow seen in plain radiography is intra- or extra-urinary. This point is often clarified by double exposure of the same plate by shifting the plate a few centimeters between exposures. If the shadow is intra-urinary it will be in contact with the radiograph catheter in both exposures.

Pyelography and ureteropyelography are very important and if done with care and precision are painless. With the various preparations at our disposal the author never hesitates to do bilateral pyelograms if such are indicated; it saves time and expense and gives great aid in the completeness of the examination.

Their interpretation requires a trained eye and experience in surgical conditions, which may be complete prostatectomy, or by prostatic resection. Be it said that not yet in the minds of all surgical urologists is the question settled as to the proper procedures in many cases of obstruction of the bladder neck.

3. Urge restraint upon some of the younger urologists, who see naught but an operating fee before their eyes, in attempting "as a last resort" to do "an operation immediately" because of the subjective symptoms presenting. By so doing they bring discredit on our group, in not utilizing consultation or conversation with the medical man, who also has a partial field in our work, especially in the terminal heart and kidney lesions; as well as consulting with their seniors in urological work.

For example: As urologists of a surgical mind we must not build up in ourselves the thought that we know also all there is to be known of the medical aspect following obstructions of the bladder neck—and while we may know quite well some of the re-

note results, learned from bitter experience, yet medical consultation many times might save a patient if we but had an excellent consultant in medicine at our command, who was at least partially familiar with our problems.

The ultimate diagnosis of the type of obstruction at the neck of the bladder, with an eye to fineness of after-result is one of judgment in weighing the factors which we can elucidate. All these factors must be found out and weighed, and cannot be predicated on a single factor for the outcome. Many times, however, the few that are found at a single examination may furnish reasoning for a false decision. Too frequently, also, do we have our hands tied in making our thorough evaluation. By the patient because of time, expense or pain—in our own or some one's previous examination. Or by the physician who is too little versed in such lesions and may have had one friend or patient who came through some type of operation on a gambler's chance, and who had the same outward symptoms. And this patient had been sufficiently bettered apparently, and temporarily to negate further work, or to refuse a second opportunity to thoroughly restore him to health.

The author is not given to quoting statistics on large numbers of cases, for perusal of the literature bring only repetitions in papers and the hundreds or thousands do not occur in the practice of a urologist, save in the largest of centers, but he can speak as of the ordinary run in one center, where diverse opinions are rampant.

Up-State cases are met in emergencies mostly, because we cannot impress in general on the large group of medical practitioners the necessity of giving the urological surgeon a fighting first chance to see a patient. And the confines of practice are too narrow for the public to appreciate the hardships undergone on the part of a real physician in attempting to persuade a patient to seek immediate aid, when in past years an unfortunate outcome in the little village has carried away a well-known citizen, who dallied too long in his decision and then, in extremis, could not be recalled from the downward path that he, perhaps with his physician, had laid out.

Education has yet much to do with bringing knowledge to the public in general, before we have reached our goal in saving many lives for longer service to the communities, and the special societies are re-

served for developing the newer and more modern ways of surgical diagnosis and modifications of surgical technic.

That is one reason why we still see the use of one or more aspects of physiotherapy tried before a patient reaches our hands for technical judgment, and much of this we may find to be the fault of advertising on the part of commercial houses.

There seems to be no essential need to give the complete list of those lesions which may block the bladder neck, as so many excellent textbooks and articles in the journals have been written on the symptoms and diagnosis, as almost to bewilder the medical man, who faces the gamut of so many and such increasing types of diseases, and their discussions as to various routines to be pursued.

And yet, if we can impress on the medical man and through him get to the public, to utilize the time saved now by 'phone, by auto, by good roads and by the press, and expend it in constant reading of his medical journals, and now and again in educative talks to his community, after close preparation of his subject, his own increased knowledge and that of the community will well repay him in economic return.

While I have said most of what we know may be gathered from medical journals and from textbooks, I yet must not belittle the individualism of each and every specialist and practitioner in medicine.

Nor would I insinuate that reason and judgment with mechanical skill are to be obtained from these textbooks, and so we hark back to the two primary factors, the early diagnosis and evaluation of a group of symptoms beginning slowly in a patient, or with a volcanic type eruption of sudden onset, and the cool judgment of the competent urological consultant.

So it is in that specialty where are found the individualists who develop and reach out with new thoughts to the betterment of the profession in knowledge and new ways of skill, to the relief of humanity.

And hence, we have our own leaders in our own fields, who are far in advance in doing, and by their efforts in a trial-and-error manner, or by strict scientific reasoning give us all an uplift, in concert with those scientific men who have to do with the making of our surgical appliances.

There is a vast difference between the slow, insidious development and the urinary

history as carefully noted, of an enlarging prostate, and that of the sharp staccato note sounded when a calculus blocks the internal meatus, or a carcinoma suddenly shuts off the stream in an unobserving patient.

And likewise there is time given to thoroughly examine the first type of case, even though the practitioner is remote from the finer instruments of diagnosis, and to discuss at length with the patient the probable outcome. While in the latter type the first move must be to give immediate aid in relieving the distended bladder and reestablishing the flow of urine either per viam naturalem, or through an artificial new divergence.

The physician must be thoroughly familiar with these symptoms and linger not in judgment as to what should be done in any case. Many times the first few hours lost in a "let's-wait-and-see-how-he-is-to-morrow" hesitancy spells extreme disaster for the patient; and the aftermath is of the making by the doctor who has first seen the case, and not usually upon the man chosen to give relief.

In a general way, we may divide the obstructive uropathies of the bladder neck region into 4 groups:

1. The congenital lesion seen as:
 - Double bladder.
 - Patent urachus and urachal cysts.
 - Congenital diverticulæ.
 - Congenital cysts at the bladder neck.
 - Beginning in infancy and developing more fully later.
 - Congenital valves of the prostate.
 - Neurological birth lesions.
 - Spina bifida and meningocele.
2. Pathological developing lesions:
 - From traumatism as ruptures, fistulae, and punctures, as well as post-traumatic scars.
 - Calculi in bladder or lower ureter.
 - Hypertrophy of the prostate.
 - Tumors near the bladder neck.
 - Acquired diverticulæ.
3. Foreign bodies introduced into the bladder, in men mostly in mid- and later life and in very young female children:
 - A loaded rectum in men or women.
 - Pressure from external growths. Especially in women from uterine or ovarian cause.
 - Pregnancy pressure as is evidenced occasionally, etc.
4. Infectious processes:

Infections involving the interior of the viscus itself, as cystitis with contractions and deformities of the bladder neck, with bars, sphincter sclerosis, reduplication of the mucous membrane, postoperative neglect, extension from the seminal vesicles; prostatitis, acute or chronic, with periprostatic abscesses; or abscesses adjacent to the neck.

Nervous lesions as syringomyelia, syphilis and its after effects, spinal or cerebral. Toxic effects on brain and cord, of diabetes, pernicious anemia, myelitis, cerebral or cord hemorrhages from antecedent disease.

It would be beyond the scope of this short treatise to describe the manner in which urological diagnosticians must work out each case of such a group. This should rather be reserved for the bedside consultations in assistance to our brother practitioners.

And yet, by such simple assistance can relief be given to these patients along the urological line of work, and it is amazing that the specialist is not sought for in hundreds of cases still existing and constantly coming to the knowledge of the physician.

As one example to be picked from all the rest, the author would dwell on two phases of this work which has leaped forward in the last three years to an amazing and marvelous degree.

The writer ventures to say, without contradiction, that no physician exists who has not had upon his call list a male patient with a prostatic enlargement, one with a sclerotic sphincter, with a median bar, or one with a bladder nerve lesion, anyone of which he has observed almost from its inception.

One can readily see, therefore, that the discussion in this paper should be limited to the more common conditions and in a general way reserving for the individuals in the audience to bring up special points gained from experience. By the percentage method we reason that in the clinical order in which cases are seen there come:

1. Prostatic hypertrophy, simple or malignant.
2. Median bars, mostly of acquired type.
3. Sclerotic or fibrotic sphincters, mostly of acquired type, following primary or secondary intracystic infection. Seen in men and women as well.
4. Neurological lesions such as tabes

dorsalis (which seems to be lessening in number), transverse myelitis, and traumatic lesions.

As a guide to the study of these conditions and as to what should be their ultimate outcome, certain factors should be set up and satisfied in the study of any one of these cases.

Many physicians are apt reasoners in diagnosis with little need of mechanical or laboratory aids. Others must avail themselves of every possible aid before satisfying themselves as to proper procedure. While still others, playing the rôle of part-surgeon and part-physician, in many instances spend too little time at either rôle to perfect themselves in this specialty and the ultimate need of a good diagnosis.

As a set-up it may be said that the following should be satisfied in seeing a case through from the beginning to the end:

1. A critical history of the patient, without reservations on the part of attending physician, or of the patient, in any degree.

2. A critical study of the patient by the physician and again by the consultant, not delegating the technical parts of the study to some distant laboratory whence time and change of material enter in, nor "cutting the corners" in one's reasoning "to save time." Far preferable is it in many instances to transport a patient with such a condition to the center of work rather than to bring the laborer in the center out to the patient's bedside.

3. A tentative diagnosis having been made, its accuracy must be checked with all possible means at command and any errors discovered must be revised.

4. A decision must be made as to whether to operate or not, as predicated on the absolute findings, reviewing one's personal errors in similar cases and those of others as known in the literature, together with the risks at stake, and making the patient fully cognizant of the same.

5. The discussion as to the proposed type of operation to be done. This naturally will rest on the symptoms present, the lesion diagnosed, and the deftness of the operator, both from a mechanical and urological standpoint. The question should be thoroughly understood as to whether the operation is aimed at a cure or is to be followed with other steps and whether it will be permanent or merely palliative.

6. Due consideration of any preliminary care if time and condition allow, to utilize many or all of the accessory diag-

nostic means available, with generous consultation as to the probabilities in the case to protect the physician and the operator throughout the course of the treatment.

7. Due consideration in advance of the operation, as to the aftercare which must be thought through, allowing immediate flexibility for emergency.

8. Finally, the postoperative result must be reviewed for several years, attending physician and urologist cooperating, in order to establish a firmer consideration of help which may be afforded in the minds of the public and of the skeptical physicians.

With these rules in mind, which every physician should demand of his consultant and operator, let us take up our four groups:

1. *Prostatic Hypertrophy of Simple Type.*—The symptoms of this are now commonly recognized, but not sufficiently evaluated, by every doctor in this State and increasingly by many laymen.

The earliest medical history deals with this lesion, the earliest illustrated and described autopsies show it.

To be sure, clinical experiments were done in ligation, section, or in enucleation of the vas, as well as simple perineal or suprapubic cystotomies, before sufficient statistics could be collected to show that such efforts were of little avail. The earliest operative removal was a one-stage suprapubic enucleation of a part, or parts, of the gland, later followed by total enucleation.

Much later there followed the perineal enucleation perfected and described in its highest degree by Young, and for a long while the pendulum hovered in this direction. It was taught far and wide and successes were met with, especially in the hands of the master urologists, even though these earlier cases were usually far advanced with heart and kidney lesion from the obstruction. Physicians were reluctant to recommend operation, because of the high death rate, persistent fistulae, incontinence, etc. Still, progress was made and slowly some of the necessary physiology and pathology became known. Intra-urethral drainage came into vogue, and then preliminary catheter drainage, or suprapubic drainage, became a fixed procedure.

Eventually, the suprapubic method again was taken up, but now in two stages, and with some light given by our medical and

laboratory practitioners, in the physiology, cardiology, chemistry, and common-sense reasoning of this condition on the body in general.

And at present, this group of procedures is chosen successfully by the majority of operators.

Each of the above has its advantages and disadvantages, as the variations in the types of cases, and the adeptness of operators is considered.

Where a patient is a good surgical risk, there should be no question but that the total enucleation of the gland is the sanest, wisest, most surgical of procedures. For it gives the relief sought and the benefit to the surgeon and the pathologist of knowing whether the hidden nodule of malignancy has been taken out; and furthermore, it aids in the postoperative outline of treatment.

But recently, the operation of transurethral resection has been forced to the forefront as being the operation of choice.

A year or so ago its advocates preached its use for all cases and with apparent amazing results from a single session.

It was and is being done by all sorts of operators and mechanics who little understood, and who are just beginning to realize, the physiological and pathological dangers, and even the operative technical skill required.

It now has progressed to the point where certain negated cases are being correlated and published as being better fitted for the older total enucleation. The various modalities of the electric current are being understood. And even to-day we note that several successive stages of operation or repeats are advocated by some of the best adherents of this method.

The action of the current on varying types of tissue is now better understood, as well as the reaction of the remaining tissue far away from the site of operation, which has been partially coagulated, charred, or necrosed.

Our bacteriological and postoperative studies have broadened our concepts of shock in such cases; our ideas of infection and its action on the body postoperatively in these cases is undergoing change. And our preliminary and postoperative examinations are being amplified in wider directions, because of the newer lessons learned.

By this method patients may be operated earliest who refuse a total enuclea-

tion even when in good operative health and may be given, at least temporary if not permanent relief for some years, provided "the medical man or the consultant can outguess the gland in its direction of enlargement."

It is cheapest economically in time, money, and hospitalization.

It seems to be best suited to the median lobe or to the prostatic bar type of enlargement. When well done in one or two stages, it seems marvelous, but of course time yet has to tell.

Perfected by Davis, McCarthy, Caulk, Alcock, and many others, we have yet to remember that there is much to study and learn as quoted from an article by Herman and Green in the *Journal of the American Medical Association*, Vol. 101, No. 18, who say: "The mechanical problem depends on size, shape, and location of obstructive mass, and the difficulties and dangers increase in resection in almost direct ratio with the vertical diameter of the tumor."

Its universal adoption by all types of operators cannot be but a repetition of the old perineal days, but fortunately, the preliminary expense of equipment may forbid its rapid utilization, save in the hands of a few, from whose experiences we are now getting authentic reports. It is not for all types of cases by a large percentage, but is of inestimable value in the properly selected ones.

The apparent ease of manipulation of these newer instruments is apt to lead the novice astray—with disastrous results. So, it behooves us as a group of strictly urological mind to advocate caution and slowness, rather than to preach to our juniors "there is but one operation and we are its prophets."

In the accurately diagnosed malignant prostate, however, with our present command of radium and x-ray, and the simplicity of implantations, no greater boon has come to humanity than the resection type of operation in the majority of cases coupled with the use of the above adjuvants. In this condition a gutter can be grooved out of the malignant mass, thus giving freedom of drainage, with many times a longer action of the sphincter before its involvement, and thus lessening cases of the older type of suprapubic cystotomy and the wearing of a suprapubic drainage tube with all its dangers and inconveniences until the demise of the patient.

This resection type of operation can be repeated without the danger of metastatic implantations, and while the disease is not stopped in progression, save as the adjuvants of radium and x-ray assist, yet the ultimate end, the comfort of the patient, is maintained and prolonged.

2. *Median Bars.*—However, when we come to this second group of median bars, we must adopt a different attitude, because of the newer instruments, and even we ourselves must become more adept in differential diagnosis.

This lesion is usually of the acquired type, though it may be overlooked as slowly progressing from early youth, until we are warned by the patient's history of the constant little pool of infection which gives us the continuous dirty urine and increase in number of voidings with all the symptoms of a cystitis, as well as later possibly the occasional pyelitic symptoms.

For many months or years this may progress with the patient seeking relief from many physicians for a "cystitis." And until recent times I venture that not one of us is there who has not missed out on many such cases, though we have reasoned in vain to discover the cause of the syndrome presented.

Too few of such cases have come to cystoscopy as yet, for they can drag along in their own way using one urinary antiseptic after another, as in the present history of chronic constipation and its many vaunted specifics, or the many combinations of alkalies for the so-called acidosis of the intestinal tract.

As a group we have not reached our practitioners to assure them of the relief we can offer, quickly, accurately, and permanently with the shortest of stays in the hospital and the abatement of all symptoms.

In this class of cases the operator must know his bladder and his landmarks most accurately. Where formerly the cold punch was used, and even now the visual cautery punch might still be used, the case of the new cauterizing and coagulating currents with the accuracy of visual manipulation in removing a halfmoon piece or more of the obstructing bar, bespeaks the opening up of a field long neglected and much mistakenly diagnosed heretofore.

But we must become versed anew in our electrical knowledge and beware of our currents!

For there is a milliamperage to be

learned for the prostatic resection, and another for this median bar, and for each a different strength in the after-coagulation. Where our sense of touch with the punch was our previous guide, it is now the retinal rods and cones we must depend on, and no operator of dimmed sight should dare attempt the use of so dangerous an agent.

Clinical reports now being taken from pigeon holes bespeak the successes and failures in this newer field and by the same token fewer bladders are being opened for the supposed prostatic condition, to the dismay of the operator who had not studied his case sufficiently.

But these closer studies of increasing accuracy will all tend to clear up one more of the common obstructive uropathies.

3. *The Sclerotic or Fibrotic Sphincter.*—These cases also fall into a category once neglected, or relegated by the urologist back to the home physician with the advice to use the Van Buren sound, or the Kollman dilator as being the easiest way out for a condition not accurately diagnosed. And how many have been the poor victims who have been sounded and dilated year after year to eternity, in a large percentage of cases to their detriment and not to their betterment, owing to too little of actual visual search.

Part of this again may be attributed to early instruments of poor type, which have been improved so rapidly in these last few years, while again credit must be given to our own group in seeking out accuracy of diagnosis and amelioration far different from the old medical (or forceful surgical) dilation, sphincter section, or complete ablation.

The dribbler can now be made permanently leak-proof in the majority of cases and his increasing cystitis can be stayed and bettered, provided the primary causal factor is removed, as usually seen in an infection higher up in the tract.

While used as a temporary expedient the higher infection may be treated at the same time.

The patient with the chronically distended bladder due to this lesion may be restored once more to a normal schedule, while the one who has lost control and has the contracted type of bladder, if seen before infiltration of his deeper bladder tissues can be assured of a reasonable carrying capacity after patient hydraulic dilation.

virulent catarrhs of this area, depends on a normal adult mucosa and high air-containing capacity. During the period of change from the infantile ear to the adult type every infection of the nasopharynx must influence to a greater or less extent, the normal change of the mucosa. An adult may have nasopharyngitis, but an infant has nasopharyngo-otitis media. The embryonic mucosa will under good conditions change into a healthy adult type, but if during the period of this development, it suffers from an acute infection, areas of the mucosa will remain in the embryonic type. These pads of embryonic mucosa, and they have been seen in old age at post-mortem, are much more susceptible to infections, and thus we see ears that are continually flaring up even with the mildest attacks of rhinitis, nasopharyngitis, and pharyngitis; they, too, are probably a factor in those suppurative cases which become chronic. Every inflammatory attack leaves at least some slight change in the tympanic cavity and it is the summation of these "subminimal" changes, which eventually produce a case of the hard of hearing. One believes, that not otologists alone, but physicians in all departments of medicine are prone to treat too lightly *seemingly* mild infections, those that produce mild reactions and because of this are not localized and sometimes produce grave results.

There is a considerable group of pediatricians and physicians, too, who sincerely believe in letting infections of the middle ear run their course. They believe in treating them palliatively and letting the ears rupture spontaneously. They say they get better. They do not have any more cases of surgical mastoiditis than those who have paracenteses done. The point of this group seems to be to avoid either a paracentesis or a mastoid operation, and if this has been accomplished, then there is great rejoicing in the camp. No thought, however, has been given, toward function of the ear, and after all the patient is interested in just one thing, later in life, and that is the hearing. There is no doubt in the writer's mind that both paracentesis and mastoid exenteration, do save the tympanic mucosa many times and thus save the hearing. He does not believe that paracenteses will cause a surgical mastoiditis. He does believe that now and then it may prevent one.

The paracentesis will do the following:

1. It will relieve pain and, by so doing,

the patient will get rest and sleep, will take food and fluids. The discharge will run out of the external auditory canal, instead of dripping by way of the eustachian tube into the throat and being swallowed possibly produce gastro-enteritis. Not all agree on this.

2. It will protect the mucosa of the tympanic cavity from further lesions due to autolytic digestion by the pus under pressure, for surely if pus can digest its way through the membrana tympani, as it does in a measure to produce spontaneous perforations, it can at the same time produce similar lesions elsewhere in the cavity. Many of these lesions may be in silent areas, but should they occur in the vulnerable areas, the damage produced is irreparable due to scar tissue formation.

3. By free drainage from the mastoid the mucosa may be saved, that pneumatization be preserved and continue at least in places, so that we may have some cells in the mastoid rather than a sclerosed one.

4. The symptoms of meningismus in an infant subside readily after a paracentesis.

The author believes that impaired hearing limits probably the efficiency of the individual much more in earning a living than many other conditions, which stimulate the medical profession to much more activity to correct. The impairment of hearing is our problem and our responsibility and it is for us to educate the laity and the profession, that they will see our point of view, *viz.*, the saving of the hearing.

ANATOMICAL VARIATIONS OF THE MIDDLE EAR IN THE INFANT FROM THE ADULT

Space does not permit enumeration of all the differences in the anatomy of the ear of the infant from that of the adult. We shall therefore consider merely those of the middle ear.

MIDDLE EAR

(A) Eustachian tube:

1. No bony eustachian tube.
2. It is relatively shorter and relatively larger in bore, therefore more of a drainage tube; pus goes to pharynx, is swallowed.

N.B. Because there is no bony eustachian tube, swallowing irritates a tender tympanic cavity, when infected, due to pulling of the tensor and levator palati muscles which open the tube on swallowing. The child refuses food and fluids, loses weight rapidly.

(B) Tympanic cavity

1 The membrana tympani is 3 to 6 times thicker in the infant than in the adult, therefore it does not rupture so quickly as in the adult, because of

(a) thickness, it may go 6 to 8 days without rupturing,

(b) the eustachian tube being so short and so large in bore acts as a drainage tube, therefore intratympanic pressure is less in infant's ear, and there is less tendency to rupture

2 The tympanic cavity at birth is really not a cavity but is filled with embryonic mucosa which gradually changes to the adult type of mucosa. We have a mesotympanum and hypotympanum at 6 months, mastoid antrum at 8 months, attic at end of first year, adult type of mastoid at 4 to 6 years

(C) The tegmen tympani presents a suture between the squamous and petrous part of the bone, here in infancy is a blood sinus. Thus here the dura is in close association with the tympanic cavity

(D) Mastoid antrum. At birth there is no mastoid process, the antrum is all that is present. The mastoid antrum, tympanic space and internal ear are almost adult size at birth. Thickness of lateral antral wall is 2 mm, frequently closed by cartilage hence we get subperiosteal abscesses early in infants

NASOPHARYNX

Is relatively smaller in the infant than the adult. This fact together with the very short and wide open eustachian tube, gives us actually a closer anatomical relationship between the tympanic cavity and the nasopharynx in the infant than in the adult. Moreover we always have added to the nasopharynx the adenoid which makes the free space smaller all this at a time, when the patient is peculiarly subject to the many infectious diseases—colds and sore throats. Now then may it not be well said if an infant has a cold in the head it has an otitis media?

PATHOLOGY

Catarrhal attacks not sufficient to produce enough exudate to escape to the free spaces produce some change in the mucosa after about three or four attacks, and thus we see changes in the membrana tympani.

We have all grades of severity of catarrhal attacks up to and including simple otitis media, which produces a little or more exudate free in the tympanic cavity. This exudate consists of serum and mucus. The serum is more or less absorbed or escapes down the eustachian tube. The mucus is retained in little or greater amounts and remains as a more or less sterile foreign body which by virtue of its presence acts as a slight irritant causing itself to be invaded by connective tissue cells and or-

ganized forming a scar. Subsequent attacks cause more scars and adhesions.

This fibrous tissue can take on activity even without an inflammation and proliferate after the type of a fibroma, it can fill the tympanic cavity and even invade the cochlea by way of the round window and thus produce internal ear disease (Alexander). Ruttin had a dog stone deaf, yet he had a functioning vestibular apparatus so that he could run and jump and do tricks. Ruttin tested out the vestibular apparatus, producing normal responses. When the dog died Ruttin posted him and found both cochleae filled with fibrous tissue, the semicircular canals intact.

On examination of the tympanic cavity and eustachian tube one sees many ridges and concavities in the floor of the tympanic cavity and in the eustachian tube. Hence there are numerous places for mucus to lodge and to become organized, making it possible for further progress in subsequent attacks. The inner wall of the tympanic cavity has niches also, namely, in the region of the round window, the oval window, the sinus tympani and the fossula subfenestra rotunda. Here globules of mucus may be retained and organized, and from these areas the fibrous tissue can proliferate.

On examination of the tympanic cavity by far the greatest extent of the walls of the cavity could be classed as a silent area. There could be lesions—ulcers in an acute active inflammation or later, healed scars which would produce no symptoms—but surely the regions of the round window and oval window would not tolerate a lesion without manifesting itself by symptoms, viz, deafness and tinnitus, deafness of the internal ear type at least eventually, if not early. The lesion at first being of the middle ear type. We are all familiar with the markedly retracted drum membrane, which is held fixed by adhesions. It would not be difficult to visualize an ear with a fibrous tissue lesion at the oval window or round window, not involving the membrana tympani. This type of lesion the author calls also chronic adhesive otitis media.

Our difficulties are many

1 The child may be born with a foreign-body otitis due to liquor amnii, or meconium forced into the eustachian tube or tympanic cavity during its voyage through the birth canal.

2. Because the nasopharynx of the infant is relatively smaller than the adult, being made even smaller by the presence of adenoid, because the eustachian tube is relatively shorter and is relatively larger if not actually larger in bore than that of the adult, the tympanic cavity is much more exposed to nasopharyngeal infections in the infant than in the adult.

3. It is the age when the patient is subject to acute infectious diseases.

4. We have to combat a propaganda, which is popular with many parents: the opening of the ear. A not inconsiderable group of well-meaning pediatricians and physicians very proudly proclaim that they do not open ears, they leave them alone and they get well. Their success is measured by the fact that the membrana tympani did not rupture. They are blind to the fact, that because the membrana tympani of the infant is anywhere from three to six times thicker than that of the adult, such a patient may suffer 4 to 6 or 8 days from a suppurative otitis media, without a spontaneous rupture of the drum membrane. During this time a considerable irreparable damage has taken place to the intratympanic mucosa even in the case that the ear should heal without a surgical mastoiditis.

5. Children never complain of impaired hearing, the parent or the school teacher tells us either the child is inattentive or it is deaf.

6. Unless ear symptoms send the young patient to the otologist, we do not see these early cases, and hence are powerless to help the patient at this important time.

7. In the pediatric clinic it would seem that the child should have the benefit routinely of the judgment of the otological department rather than be forced to wait until the pediatrician decides to call in help.

CONCLUSIONS

1. A healthy ear depends upon a healthy nose, nasopharynx, and pharynx, and our attention and treatment must be directed to these in all involvements of the ear.

2. Up to the present time there is no positive way of preventing colds in the head and epidemics of influenza; therefore, as is the case in the acute infectious diseases, we should endeavor to impress upon the laity the necessity of strict isolation in all these cases, thus limiting the spread of these infections and the number of involvements of the ear.

3. The writer believes that it would be a good thing to give all patients who have had at least a sensation of fullness in the ear, during upper respiratory infections, a Politzer inflation two to four times, say two weeks after recovery from the so-called cold in the head, to dislodge serum or mucus, that might become organized and be the beginning of progressive deafness.

4. All procedures that prevent or limit acute infectious diseases with localizations in the nose and throat, are equally valuable to the ear.

5. Adenoid operations give the most help to the ear during the first four years of life. We cannot hope to influence the development of the ear, certainly after six years of life.

6. It is a poor policy in infections of the middle ear to let them take care of themselves as is done by a considerable body of well-meaning physicians; the ear may survive the infection, but there is a great tendency for impairment of function.

7. Where there is marked impairment of hearing, instruction should be given early, in lip reading and in old cases; a careful selection of some instrument should be made which helps the sufferer to hear.

8. One feels that the catarrhal, the serous, and the simple forms of otitis media are probably a greater cause of impaired hearing later in life than the cases of suppurative otitis media.

In my mind the greatest measure in the prevention of Hard of Hearing would be compulsory isolation of all cases of upper respiratory infection, thereby materially reducing such complications as sinusitis, and otitis media in all of its forms.

ABSTRACT OF DISCUSSION

DR. JOHN D. CARROLL: I agree with Dr. O'Connor that early paracentesis or myringotomy is essential in reducing one of our causative factors. I believe also that as far as our section of the State is concerned the public is becoming more educated to allowing early paracentesis and the values derived thereby. It is only rarely now that I have any extended explanation to make for such procedure. We are doing many more paracenteses and are doing fewer mastoids than we did some years ago. I agree with Dr. O'Connor that many of our physicians to-day are still waiting for the ear drum to rupture spontaneously but I believe that they are lessening in their obstinacy and a few years hence we will have little trouble from that source.

The hearing of our school children is coming in for more attention by the school examiners and many of these children of tender age are being referred to doctor's offices or clinics for

examination and treatment of ear conditions. These school examinations are doing much to acquaint the parents and public in general with the need for early discovery of hearing impairment. I do believe that greater importance could be placed upon these school examinations if they were done by or under the supervision of an otologist. It has been my experience so far that many of these children after having been examined in many cases by a nurse or other attendant using the audiometer in making examinations have been reported as definitely lower in hearing in either one or both ears than actually presented itself when the patient arrived for examination and treatment. There are several factors I believe which influence such tests and are not recognized by the non otologist attempting such examination. Many of these children or their parents when questioned by me have admitted that they have had a severe head cold or sore throat at the time of or shortly previous to the examination. Such tests made under those circumstances I believe to be comparatively useless or at least erroneous.

My thoughts are in accord with those of Dr O'Connor in regard to follow up treatment after the subsidence of acute middle ear conditions. There has been a tendency in the past to overlook the sequence of impaired hearing after acute inflammatory conditions. Educating the parents as to the need for follow up treatments will tend to lessen the incidence of hearing defects from this source.

Periodic health examinations have been stressed for some years by the medical profession as a means of preventing or lessening the incidence of disease. Periodic ear examinations by a competent otologist I believe would do much to lessen the incidence of poor hearing not only in youth but in middle adult life when so many cases of catarrhal deafness coming like a thief in the night stealthily creeps upon its victim until a definite loss of hearing exists before recognized by the patient.

ESTELLE C. SAMULLSON. No doubt many of you have heard about the program in conservation of hearing of school children which has been in operation in New York City since last January. This program is sponsored and operated by the Board of Education under the CWA. The New York League for the Hard of Hearing Inc. cooperated in training the personnel and assisting Mr. Daniel Caplin, Assistant Director of Health Education, New York Department of Education who is director of the project. Almost 200 teachers were trained as audiometer technicians and teachers of lip reading. The program called for the testing of 600,000 school children. 136,000 have been tested to date. Over 4,000 have been found to have impaired hearing. The 4,000 represent the number of children discovered on the basis of three tests: two with the 4A audiometer and one with the 2A. Over 10,000 children were found to have had ear conditions such as abscesses, ringing in the ears and running ears. This is a significant figure in a discussion of prevention. May I call your further attention to the fact that the programs call for an otological examination of all children showing a hearing impairment? While the medical end of the program has not been inaugurated to date we are assured that it will be.

Such programs and activities in our school

communities should have your active support and cooperation. The school boards and propaganda agencies concerned with hearing health of school children need the otologists and welcome their suggestions and guidance. We need you too to bring about the cooperation of the family doctor.

Your State Society has a committee which is a subcommittee of the committees on public health and public relations. This subcommittee has taken for its objectives:

1 Raising the standard of otological care of children in schools for the deaf.

2 Working for conservation of hearing of all school children.

Will you work with it toward the achievement of these objectives?

DR. FRANK A. PRATT. As the otologist of the State Education Department I owe a great deal to all of you for the support and cooperation you have given to our program for the hard of hearing school children in this state. It is through your support that we have arrived at this point where we seek your fullest support for the continuance of this program that through you the education authorities may know how many children should be provided with special education—lip reading provided in the grades for the hard of hearing children and special schools, for the deaf.

The ideal would be to have an otologist for every school. As this is impossible at the present time we must continue to send all children whom we find defective to the otologist privately or to the clinic.

The policy of the Medical Inspection Bureau is that tests for hearing are given by the school nurses to day using 4A audiometers. This is a screening process only. We recommend checking these with a 2A audiometer wherever possible. We are obliged to use the material we have at hand for finding these children. This is the school nurse teacher. We have 500 throughout the state exclusive of New York City, Rochester and Buffalo. These nurses are certified by the State Education Department as school nurse teachers after taking 12 semester hours of school nurse teaching. They make the tests for acuity of hearing after receiving instruction in the use of the 4A audiometer. This instruction is limited as there is only one person to give it with very limited funds for travel and the state is large. It is inadequate. You can do much to increase the efficiency of these tests if you will get behind the movement for conservation of hearing. Your criticism is justified when you complain of the inaccuracies of these tests. You can make it constructive criticism if you will recommend for the state more audiometers and a personnel to supervise the instruction of those nurses who give the tests.

Such action on your part will not be detrimental to you.

It is further our policy to refer to you all children with a hearing loss for your examination and treatment. This is done by the school nurse and school physician. The school physician in the majority of cases is on a part time basis, inadequately paid and busy.

The method of referring these cases to you is not ideal in that each parent is notified by what we call a notification to parent or guardian blank which advises parents that the child has a defect

of hearing and that the advice of the family physician must be sought. Sending the child to the family physician is done because over a period of twenty years it has been necessary to have a method by which the advice of a physician would be obtained for all defects. In this state those other than physicians are permitted by law to correct certain types of defects. If all defects are referred to the family physician, the majority will be cared for by a physician in the field in which the defect lies (teeth, eyes, ears, etc.). The Medical Inspection Bureau of the State Education Department whose function it is to provide medical supervision of school children believes this the best way to answer the charge

of discrimination against any nonmedical groups licensed to correct defects. This therefore points more clearly to the duty of the otologists to unite in an effort for conservation of hearing of all children of preschool and school age.

To bring out the point made in Dr. O'Connor's paper in which he points to the need of conserving hearing at an early age by having the children see an otologist at the commencement of an acute ear condition, let me say that you would have the support of the Medical Inspection Bureau of the State Education Department.

Let us all work to the best of our ability and with the best tools we have for the prevention of deafness and the conservation of hearing.

OXYGEN AND ATHLETICS

Investigations show that swimmers who inhale oxygen before entering the water are able to better their previous records. The Japanese swimming team, which made a remarkable showing at the Olympic games in California in 1932, inhaled oxygen for five minutes about half an hour before competition, reports the *A. M. A. Journal*, but it cites experiments by various investigations which seem to show that better results are had if the oxygen is inhaled immediately before the swim. Tests made by P. V. Karpovitch and reported in the *Research Quarterly* of the American Physicians Education Association show that men who took two deep

oxygen inhalations just before plunging into the water were able to break their own unofficial records. Moreover, of six who could not break their own records, four did not follow instructions and exhaled the oxygen before striking the water. However, swimmers who inhaled oxygen for a period of from three to five minutes and discontinued it from four to five minutes before a hundred yard swim found that the inhalation had no noticeable effect on the speed of swimming. It was found that the inhalation of oxygen after any athletic activity hastened recovery. Karpovitch concludes that oxygen taken immediately before strenuous exercise has little effect.

"A MODERN DR. MacLURE"

The wide admiration for the efforts of Dr. Allan R. Dafoe in keeping all the Dionne quintuplets alive so long gives interest to a letter from the doctor which appears in the *Bulletin of the Academy of Medicine of Cleveland* under the above title. We find it quoted in the *Bulletin of the Medical Society of the County of Kings*. The Cleveland editor remarks that: "It is an inspiration to those doctors who work surrounded with all the best modern hospital equipment to realize that men can practice in primitive surroundings with such common sense and efficiency as is shown in this letter." Dr. Dafoe's letter runs as follows: "I feel that I must answer your letter. Babies were born in one-half hour; two complete in sacs. These remained for some minutes while I tied off the first three. They looked interesting swimming around and kicking. The mother was apparently dying and pulseless. I expressed placenta. This was common to all cords which entered the mass. Apparently a one-ovum pregnancy. It looked no different from a one-child delivery. Placenta was destroyed by the midwives. I was too busy with the mother to pay any more attention to the babies, etc. She recovered after an hour's work. Pituitrin, ergot, holding uterus, etc.—Am very busy these days.

"I am glad that my few notes met with your approval. I have been busy, and perhaps they are not too plain.

"At present the children are improving slowly, but are a handful. Difficult to make them drink enough. They are fed every two hours, temper-

ature of incubators is now kept at 82 degrees, using Taylor Humidguides to keep the moisture at 50 to 55. Three single incubators, and one large one to hold two. Oxygen, 96 per cent, and CO₂, 5 per cent, administered four or five times a day as a routine. Oftener if they show cyanosis. Rum, one drop in milk—if and when needed as a stimulant. Children are only handled once a day to be oiled and cleaned and weighed. No one, of course, is allowed near them except the nurses with gown and mask. My inspections are only made through glass.

"The mother in previous pregnancies (six) used to stay in bed only for three or four days. Difficult to keep her there now.

"Human milk is furnished me daily from Sick Children's Hospital, Toronto. Children are now taking 45 ounces per 24 hours.

"Sometime when not too busy I will try to make a full report which will probably be published in the *Canadian Medical Journal*. I see no objection to publishing a few notes in your *Bulletin*. Use your own judgment."

The Dionne quintuplets have started such a scare that a California man has taken out an insurance policy for \$1000 with Lloyds against the arrival of twins in his home this fall.

A bright newspaper writer, noting that "the Mayo people say the same germ causes sneezing and sleeping sickness," remarks dryly that "he must interfere with himself a lot."

THE BIOPSYCHIC APPROACH TO DISEASES OF THE MIND. ITS DEPENDENCE ON NEUROLOGY AND GENERAL MEDICINE

FOSTER KENNEDY, M D FRS (*Edin*)

New York City

Neuropsychiatry by its very nature must pervade all medicine, neurology must rest upon it, and must be the base of psychiatry. We who study these things must concern ourselves with the general field. You remember when Peter rested on the roof-top he saw a great sheet let down from Heaven, full of all manner of creeping and crawling things. Shrinking from them he heard a Voice from on high saying, "Call nothing that I have created common or unclean." In the past century neurologists were busy collecting, classifying and, as their often unappreciative colleagues would say, "labeling" specimens of neural disorders. Even to day many physicians point at us an unwitting finger, thinking us an academic lot, full of wise saws but in the main signifying nothing. This view is long outgrown, far behind the realities of our employment. We have viewed and learned the flora on the ground's surface, tabulated and brought them into the scheme of law. Now is the task of digging into the ground to find the roots from which plants spring and of analyzing the soil—often heavy and seemingly unprofitable labor but work which is the very stuff of medicine and on which will one day be established a true pathology of mind.

May we here examine a little the detail of this pretentious statement? For example, think of the role of focal infections in the production, often quickly, often at long last, of degeneration in the central nervous system. Abscessed teeth and chronic sepsis of the tonsils by perineural lymphogenous infections cause cervical spinal arachnoiditis with cord compression and slowly progressive paraplegia. Carbuncle of the neck, by lighting an almost instantaneous fuse, may cause an explosion in the upper spinal segments with transverse myelitis and quadriplegia. Diphtheritic sores of the hand have been shown to cause radiculitis and spinal paralysis of the affected arm, while the same diphtheritic sores on the thigh, throughout the British Forces in Mesopotamia, gave rise to cauda equina neuritis with double

dropped feet and paralysis of the sphincters. Kinnier Wilson has shown the part played by chronic lead poisoning in painters and cable layers in the later production of amyotrophic lateral sclerosis. If one neural poison can cause central cell degeneration in this manner, the same road of invasion is open to others whose nature still lies hidden from us.

Lately a woman was seen by us who gave a history of recurrent herpes zoster in the left 2nd and 3rd lumbar root skin areas of the left upper thigh. The painful eruption had appeared regularly for 16 months in the first days of each menstrual period. She had consulted many physicians of the skin with slight symptomatic success. The clue to her condition was the discovery of an infected Bartholin cyst in the left labium which, aggravated at the period, caused an ascending inflammation of the appropriate roots and posterior spinal ganglia.

Again a man was seen who had extensive anterior horn muscular atrophy of the legs with fibrillary twitching, usually thought characteristic of progressive muscular atrophy. The absence of any signs of involvement of the cervical segments, however, caused us to suspect the existence of a local infecting focus. The cure of a chronic prostatic abscess, in this case, resulted in recovery of function in the lower spinal segments.

Last year a soldier had eight upper teeth removed at one time under local anesthesia. Three days later he began to have severe neck pain and occipital headache and, in two weeks, he died of meningitis. The road for bacterial invasion of the brain membranes had been opened through overconfidence in modern dentistry applied to infected tissues.

One may point out the dependence of some spinal cord degenerations on long-standing achylia gastrica which, in its turn, may depend upon a chronic cholecystitis.

A dozen years ago a violent epidemic of polyneuritis with many scores of fatalities was traced to streptococcal milk. The dependence of other inexplicable

forms of neuritides is often found in nutritional deficiency, not due to inadequate diet but to inadequate assimilation through deterioration of function in the mucous membrane of the alimentary canal.

But there is no need to pile Pelion on Ossa; we must realize that the causes of neural degenerations lie often in infections of other tissues. Within the lifetime of all here, paresis and tabes have been proven to be caused by lues and only by lues; but most of the older men as students were instructed that these two nervous diseases might come from overwork and exposure—presumably to the winds of Heaven! I was told as a student that paralysis agitans was "a neurosis" without organic basis. We know now its cellular pathology and much of its infective origin. Asthma was to me at college akin to the vapors of a still earlier day. Now we understand its allergic etiology and are beginning to sense the great part individual sensitiveness to specific proteins may play in many cases of palsy, blindness, and various obscure forms of cerebral illness.

So, we neurologists live in no ivory tower. We scurry over and delve in the fields of internal medicine and must also try to throw search-lights through the tenebrous fog of endocrinological fact and fable. So, too, we must deal with the aberrations of all the special senses. We must try to bare the causes of many cases of blindness, of discrete losses of vision, of diplopias and, often enough, of simulated disease. We must try to give a reason for subjective visual phenomena, like visual fits or the more complex hallucinations of men and things associated with disordered function in the temporosphenoidal lobe. We must know enough about sinus disease to distinguish between the pain caused by osteitis of the floor of an antrum and that of trigeminal neuralgia and between the localized headache due to pus in a sphenoidal sinus and a unilateral migraine. We neurologists must examine the ears *ourselves* and later secure skilled aid from the expert. We have to decide the significance of subjective ear noises and the significance of islands of lost hearing, to appraise labyrinthine efficiency and distinguish errors in semicircular canal mechanism from those of the cerebellar system. Errors in respiratory rhythm and palsies of the vocal cords, together with bulbar palsies and hysterical aphonias give us a link with the laryngologist. Thus the senses of taste,

touch, and smell, and the vagaries of speech all bring grist to our mill and we must grind thoroughly if we would make good bread.

We cannot busy ourselves with the spinal cord without acquaintance with its bony covering; nor can we deal with paralyzed members with no concern for the resources of the orthopedic surgeon in their cure. At times we can elucidate the cause of sciatic pain as being due to a tumor of the epiconus, not easily susceptible to spinal fusion, and aid by the diagnosis of dystonia musculorum in the orthopedic problem of the resultant disordered joint.

The palsies of the sphincters and the failure of the sexual reflex bring us into alliance and understanding with the genito-urinary surgeon, but it is in the great problem of incurable pain that we can perhaps be of most assistance. Inoperable pelvic cancer, prostatic or uterine, may be made somewhat bearable by the operation of chordotomy, the division in the upper dorsal region of the tracts carrying pain impulses to the brain and consciousness. This operation, in proper hands, is no more arduous to the patient than is an exploratory laparotomy or an appendectomy; it causes no motor palsy, no essential sensory loss, merely a transient sphincter disturbance and will secure the patient from most of the rigors of morphine life. There is nothing to be said for the expectant treatment of bladder or womb cancer. When the diagnosis has been established and local treatment exhausted, chordotomy should be done before morphine addiction has occurred.

All the specific fevers have their nervous concomitants, paralyses due to cerebral thromboses, neuritis, deliria, and psychoses. These latter, mark you, are the outcome of infection and fever. Is it not strange in us that a patient with pneumonia or typhus who, harrassed by delusions of imminent destruction, throws himself from a window is classified as delirious from fever, while the same psychic situation with no *obvious* intoxication may be called paranoiac, the organic pathology of which most psychiatrists deny? One patient is said to have a disease of the body, the other a disease of the mind. This is at once loose and dogmatic thinking. We must educe a pathology of mental disease through Medicine; the effort to do so through philosophy and psychology has failed. They are useful till our knowledge of the body will

have grown to larger stature. In therapeutics they deal well enough with symptoms, but a sharper sword is to-day being forged by Medicine to deal with the nature of mental illness itself.

Often one hears a plea from the psychologist for the consideration of the human animal as a whole. We have often heard physiologists speaking of the cerebrum, the cortex, acting as a whole. I have never been quite able to understand clearly what is meant by the physiologist when he speaks of the cortex acting as a whole. Head uses the phrase in his writings. I have always thought it a very confusing term, but I think I do understand, or approximate to understanding, what is meant by a human being acting as a whole, in that the metazoic, multicellular animal functions in each act as uniquely, in as unified a manner, as does the unicellular animal. Each behavior, each act of behavior, is the resultant of the forces that are in the organism, so that I think one may properly speak of the human being as acting as a whole, which is far from being the same as feeling or thinking as a whole.

Many lately have spoken rather adversely of Freud's philosophy, Freud's theory, as being a purely motivistic relation of human behavior. Now, unfortunately, those who speak decidedly on any side in this rather amorphous world get the reputation of being prejudiced persons.

Our antagonism, if it can be called antagonism—and it is only criticism—to psychoanalysis is not that it is wrong but that it is true only in part. It is one angle of view only. Our mind symbolizes everything we see, we see but one aspect at a time and that first and clearest that appeals to the consciousness of the observer. The important thing is to try to have more than one angle of vision, but the psychoanalyst seems to see like Polyphemus with but a single eye and one cannot but feel that there is a certain belief in their circles that they have absorbed psychiatry. The psychoanalyst feels that only he is truly a psychiatrist and that unless one is a psychoanalyst one is not a psychiatrist, and that he who is not for them is against them. This is on the banner of all religions. They suggest one has no right or power to have a notion or an idea of human personality in other terms than theirs. Shakespeare was not a psychoanalyst, Voltaire was not a psychoanalyst, George Moore and Thomas Hardy were not

psychoanalysts, but I venture to say that these men know more of the human spirit and the motivistic phenomena that prevails in the human heart than most of Freud's disciples. The great artists are perhaps the greatest of all psychiatrists. Their understanding may be better than our knowledge. So, I feel the Freudian contribution to be this. Freud has demonstrated that there is a phylogeny of personality. By that I mean that each of us is a microcosm of our race. From the egg to death we pass through stages in our body at least similar to those through which the whole race has passed. Freud has made it clear that in our emotion, in our striving, in the preponderance of this instinct over that at different periods of our lives, we have a like phylogeny of personality, that the child is a savage, that its sexual instincts emerge by gradual progression from a preoccupation with one orifice to a preoccupation with another. That is a true contribution to knowledge. Freud himself, however, has lately said that he is not sure whether it is a contribution to therapeutics but at least it does make it clear how our instincts developed inside the microcosm of each man's body. We have vestigial remains like gillslits and others like scatological tropisms, but we cannot describe the total body in terms of the one or the total personality in terms of the other.

This analysis of behavior has been, nevertheless, a great compensation against the materialism and dogma of the "cellular" epoch which perforce evolved in the nineteenth century. However, if we are to think solely in terms of this reversion to dualism, this ecclesiastical view of man, which has beset our minds and lamed our thoughts for two thousand years, if we are to think that such patterning and docketing is the whole of psychiatry then, I say, we are sinning against the Holy Ghost, the Holy Ghost of Medicine.

We must remember the plain facts of fever psychosis, the fact of glycosuria in shell-shocked soldiers. If we imagine each human being to be a single unswerving, unchanging uniformity against which stimuli are directed, and if we postulate that each such individual invariably reacts to stimuli in the same way as does every other individual, then we are saying something contrary, I am sure, to human experience and to common sense.

Individuals vary as much in their personalities and reactions as in their faces

They differ, as even Freud has stated, in their inherited endowments. I am not sure whether "inherited endowment" is an absolute fixed concept. I am even inclined to question the dogma that there is no such thing as the inheritance of acquired characteristics. Indeed, part of our trouble in this whole discussion is that we see the problem narrow and we see it short. We think in too small units of time. We cannot see the results of inheritance of acquired characteristics because of the paltry shortness of our lives and, because our eyes are holden, our minds are holden also.

There is a good deal of evidence in the animal world that such transmission of acquired characteristics exists, that a defective germinal cell will produce a defective descendant and that the defective descendant will procreate a defect in his descendant. It has been done by an injection of pulverized lens tissue of rabbits into fowls whose serum thereafter put into pregnant rabbits produced creatures with defective eyes inherited to eight generations. If that can happen in the lower animals it may happen to us; only our nervous systems are so complex, they are so much more evolved, that we cannot see them in terms of our little lifetimes.

Good heredity and the care of the stock is the most important factor in the prevention of the psychotic state. Of course, psychogenic disease does exist. There are the results of great injury, great shock, but consider in this regard the results of the greatest disasters and the greatest emotions, consider the emotions of war. The statistics of the last war, which was a great laboratory for this investigation, show that while psychoneuroses were very frequent, in the tens of thousands, there was no increase of psychoses in the troops over those afflicting the same number of people in civil life. How do you account for that? If our psychoses are produced only by biological pressure how do you account for the absence of an epidemic of psychoses in war? You cannot, Of course, the pressure of the herd, the pressure of the sex, the pressure of hunger impinge on and mould, modify and direct, the growing organism. A man, who may be a potential homosexual, may be made a complete homosexual by experience, but I believe he must be *nearly* a complete homosexual not to resist the normal trend of physiological living.

I dislike the new term "mechanistic approach." I think this word does its idea much less than justice. We do not think of using or advocating a mechanistic approach solely. What we advocate is that we should employ *all* our physiological knowledge, all our anatomical knowledge, all our social, our anthropological knowledge, our bacteriology, our histology, our morphology, bringing them in coordinated cohorts to find out the nature of the mind of man instead of limiting our approach by an arbitrary symbolistic theory. We should treat man as a dynamic and physiological whole.

Our attitude is more a biopsychic approach than a mechanistic approach. After all, who would think of trying to discover the meaning of Sight, of Vision, without examining the eyeball? Nobody. If we should think of Sight without any reference to the eye, without any reference to the physiology of the retina, with no reference to the brain tracts or to the ability of the cortex to gather up and differentiate sensations that come into it and to unify them, all purely in a physiological manner, we would know nothing of sight. Very well. What we would know of Sight, lacking such consideration, would not be Sight but esthetics, visual esthetics, and we would be dwelling in this, too, as among the Mysteries.

We all err in trying to explain the unknown by something equally unknown. We look up in the dictionary the word "vitality" and we find it means "zest"; we look up "zest" and find it means "vitality." If we do not know the meaning beforehand we may as well not open the book. All things may be viewed in several ways. The first chapter of Genesis is just as true as Edwin Clodd's "Story of Creation." We *must* believe that we cannot have intellect, dreams, or ecstasies without a fine inherited neuronc endowment. The strategic outlines and boundaries of mind are laid down by heredity, its tactical plan by social inheritance, by education and by the moulding pressures of sex, the herd and hunger. All, all may be destroyed by infection or by injury. In fine, we doctors have to remember that man is lowly in his beginning, agonized in his growing, most wonderfully and variously made in mechanism, and that there is in him a spirit that o'er-leaps the stars.

PLASTIC SURGERY IN THE REMOVAL OF EXCESSIVE CUTANEOUS TISSUES OBSTRUCTING VISION

KEITH KAHN, M.D.
New York City

The condition to be described in this paper rightfully deserves closer attention than is usually given it. Although it is the ophthalmologist who should be consulted, most patients seek the aid of the plastic surgeon; for frequently they come to be beautified rather than to have their impaired eyesight corrected.

The usual complaint of these patients is excessive growth of tissue about their eyes. In many cases the vision is unimpaired, and the unsightly tissues are removed in order to eliminate a social handicap; however, in the majority of the patients, their field of vision is partly obstructed, and in some cases it is almost completely obliterated. It is, as a rule, then only that the oculist will detect the cause of impaired vision; for he will search rather for organic defects than for mechanical abnormalities. The patients become far-sighted: they see exceptionally well at great distances, but experience considerable difficulties in focusing on objects near at hand.

There are two types of the condition: (1) the relaxed, and (2) the edematous type. In the *relaxed* type, the excessive skin is very thin and hangs like a curtain, forming a small slit between the upper and the lower lids through which the patient can see. The upper eyelid and eyelash are completely concealed. The grooved space between the eyebrow and the eyelid is obliterated (Fig. 1a). In many cases the subcutaneous tissue is *edematous*. Here, the skin forms a bulging roll over the eyelid, but because of its thickness the eyelashes are left free. If there is a great deal of relaxation, the patient finds it necessary to tilt the head backward in order to see more clearly. It is then that the condition assumes the appearance of a physiological or mechanical ptosis (Fig. 1b).

Incidence.—The yellow and brown races possess a hereditary predisposition to this condition. In the black and white races, environment seems to play a greater rôle than heredity in producing this physiological deformity. Outdoor life is a contributing factor. In the temperate zones where life is largely indoor and where artificial light is employed more frequently, the re-

dundant flesh is likely to be edematous. On the other hand, in tropical climates, where sunlight and fresh air are abundant, the offending structures are usually very thin and free from edema.

Among men, those who have to shoulder grave responsibilities, which cause them to squint or frown, are the subjects most frequently encountered. Doctors, dentists, lawyers, railroad and civil engineers, sea captains, and a large percentage of judges past 50 years of age head the list. As to women, those massaging the eyelids daily with beauty preparations are most likely to be effected. Where environment is the causative agent, the condition is seen in middle or old age, while in cases in which heredity is the predisposing factor, it is also found among younger people. In the series of cases treated by the writer, the patients' ages ranged from 19 to 71 years. The author has performed this plastic operation approximately 500 times. There were about 100 cases in whom vision was gravely obstructed, and of these 100, about 90 per cent were over middle age.

Impairment of Vision.—The vision may be impaired in the following ways:

(1) By the increased weight and prolonged pressure of the redundant flesh upon the eyeball.

(2) By obliterating part or all of the field of vision.

(3) By improperly shading the eye, which in turn results in incorrect and insufficient reception of light.

(4) By slight drooping of the lids. The tissue filling the grooved space beneath the eyebrow pushes downward on the lid, thus preventing complete elevation without special effort (lifting of eyebrows).

Removal of Tissue.—In order to determine the amount of relaxed tissue, the skin is held between the fingers while the eye is closed (Fig. 6); then, as the eye is opened, the skin is pulled outward and downward. After suddenly releasing the skin from the finger hold, one can note the extent of relaxation as the skin very slowly contracts in a vain effort to free completely the field of vision.

In order to obtain a free operating field, it is essential that the eyes remain closed

during the operation. Therefore the operation should be performed under local anesthesia. After the patient's face has been prepared, the redundant tissues are grasped in special clamps and the patient is permitted to open and close his eyes to determine if there is any undue tension and to insure comfortable closure after the clamped tissues are removed.

To produce anesthesia, the author uses 2 per cent novocaine. Very small, straight scissors are employed to remove the clamped tissue from its base, leaving a

Fig. 2.—Eyes before operation.

Fig. 3.—Same case as Fig. 2. Appearance of eyes when relaxed tissues are elevated.

Fig. 4.—Same case as Fig. 2. Ten days after operation.

Fig. 5.—Same case as Fig. 2. Nine years after operation.

Fig. 6.—Method of determining extent of relaxation.

Fig. 7.—(a) Before operation. Eyes open as patient looks slightly downward. (b) Ten days after operation.

jagged, angulated line of incision (The angulated type of incision is used to overcome the slight contraction which tends to convert it into a straight line without contracting the ends of the cut. It also breaks up and diffuses the shadow which then blends with the background, in many cases entirely eliminating any visible scar.) In the edematous cases, part of the edematous tissue is removed along with the more superficial skin layers. There is very little bleeding and therefore it is seldom necessary to clamp a bleeder—and never to ligate—except on rare occasions during the removal of tissue near the external canthus when a small branch of temporal artery is encountered. The incision is closed with No. 1 black silk, Ford single knot suture, and covered with carbolated vaselin. No dressing is applied. The patient is given a pair of dark glasses to prevent public inspection. The vaselin is renewed daily. The sutures are removed on the third or fourth day, depending upon the texture of the skin and the patient's healing ability.

After the removal of the sutures, a flexible collodion dressing is applied, this is not disturbed and will drop off of its own accord on the seventh to ninth day. The operation is without pain and the inconvenience is surprisingly small.

End Results—In regard to the improvement of vision, the results are extremely gratifying in cases which are not accompanied by organic disturbances. The rejuvenating effect upon the eyes and face is very noticeable. The patients are very enthusiastic about the results and in many cases are able to cast aside their reading glasses.

In the author's series of cases, none required a second operation.

The purpose of the writer in presenting his observations and results with this type of cases is to bring the attention of the profession to this condition as an entity in plastic surgery and to stimulate more active research in determining the exact degree of visual improvement in these cases.

769 SEVENTH AVE.

ANNOUNCEMENT

The first International Assembly of the Interstate Post Graduate Medical Association of North America to be held east of the Alleghenies is to take place in the public auditorium of Philadelphia, Pennsylvania November 5th, 6th, 7th, 8th and 9th 1934, with pre Assembly clinics on November 3rd and post Assembly clinics on November 10th in the Philadelphia Hospitals.

The public auditorium is located in the University area and across the street from the Philadelphia General Hospital, thus assuring the Assembly close access to an abundance of clinical material.

The aim of the program committee with Dr. George W. Crile as chairman is to provide for the medical profession of North America an intensive postgraduate course covering the various branches of medical science. The program

has been carefully arranged to meet the demands of the general practitioner, as well as the specialist. Extreme care has been given in the selection of the contributors and the subjects of their contributions.

The Philadelphia County Medical Society will be host to the Assembly and has arranged an excellent list of committees that will function throughout the Assembly. A most hearty invitation is extended to all members of the profession who are in good standing in their State or Provincial Societies, to be present and enjoy the hospitality of Philadelphia 'the City of Brotherly Love.' A list of distinguished teachers and clinicians who are taking part on the program will be found on page 14 advertising section of this Journal.

CANCER DEATHS UP SHARPLY

Cancer statistics just compiled for 1933 by Dr. Frederick L. Hoffman, consulting statistician show a sharp increase in mortality over 1932. Dr. Hoffman's report is published in *The Speculator* insurance publication. The figures, the report says also mark a continuation of the steady advance in the cancer mortality rate recorded annually since 1906.

'Cancer in 1932,' the report says "exacted a heavier toll of lives in American cities than ever before. Compared with 1932 there was an increase in the rate for fifty American cities with uniform records dating back to 1906 from 122.7 per 100,000 to 124.7.

'The colossal magnitude of the problem is better illustrated by the statement that in the fifty cities under review, with an aggregate population of 32,000,000 in 1933 there have been 722,274 deaths from cancer since 1906, or during a period of twenty eight years. The figures show an increase in the rate from 71.6 per 100,000 in 1906 to 100.2 in 1920 and 124.7 in 1933.

'Cancer is now the second leading cause of death, following diseases of the heart considered as a group. However disagreeable the conclusion, we apparently have not made the progress anticipated for the disease continues to increase regardless of strenuous efforts to stem its ravages in the American population."

EDITORIALS

Why the Copeland Bill Died

Many physicians have no doubt found it hard to understand why the Copeland Bill failed to pass the recent session of Congress. It was framed to protect the public against the false and fraudulent claims of the patent-medicine makers, and while the Congress seemed ready to revise and revamp our whole system of economics and politics to help business out of the slump, yet it refused to pass this measure to safeguard the people's health. This seems a rather strange attitude at the very least for a body of legislators elected to serve the public interest.

The aim of the Copeland Bill was to remedy the defects of the Food and Drug Law of 1906, which forbade the nostrum makers to print false claims on the labels of their concoctions. That law neglected, however, to bar false claims in advertising, a point soon perceived by the medicine vendors, who ran riot with glamorous statements in their ads, but sang very small on the labels. Even at that the public were protected for years by the high standard of advertising ethics maintained by the

more 4.—Same case as papers and magazines
why extravagant curative

claims. When the slump hit them, however, the high standards fell, and in the last few years the advertising pages have been sprinkled with "cures" that must have brought a sad smile to the face of the physician.

The Copeland Bill would have ended that sort of thing. It would also have put a stop to the sale of cosmetics that are injurious, some of them even causing blindness. As the session of Congress wore on, however, it became evident that the bill was not likely to pass. On May 16, Senator Copeland found it desirable to explain to the Senate that his bill was not at all the same as the "Tugwell Bill" which had "met with such violent opposition throughout the country." The attitude of the Senate, however, remained cold and Senator Copeland finally expressed the hope that if his bill did not pass, "some future, and perhaps wiser, Congress may see fit to enact it."

The mysterious demise of this measure seemed to call for something of a post-mortem examination, so the editor of this journal wrote to Senator Copeland to ask the cause of death. To this inquiry the Senator replied in no uncertain language, as follows:

"The lingering death of the Food and Drug Bill was the result of unreasonable prejudice and unbelievable selfishness.

"Prejudice against Dr. Tugwell, whose name was attached to the original bill, and, even though the Tugwell part was eliminated, had much to do with the unfriendliness of Congress.

"The selfishness of certain proprietary and cosmetic concerns was the last and perhaps the most deadly contributing cause."

This throws an illuminating ray of light on the way in which our laws are made. The failure of Congress to pass this bill is causing remark in medical circles all over the country. The out-of-date Food and Drug Act of 1906 is all that stands between the public and "the gigantic food and cosmetic and patent-remedy industries" observes a medical journal in Minnesota, and "it is obvious that these industries find aid and comfort in things as they are."

The situation is reminiscent of a scene years ago when the House Ways and Means Committee was holding hearings on a new tariff bill. Spokesmen for various interested industries were being heard, when a stranger appeared and asked permission to give his views. "Who do you represent?" the Chairman asked him. "I represent the public," he replied. The committee burst into a roar of laughter, and he was shown the door. Now we seem to have another case where everybody's interests have a hearing except the public's. We can only hope with Dr. Copeland that a future Congress will be "perhaps wiser."

Chinese Medicine

The medical customs and practices of a nation embracing one-fourth of the human race are certainly worth a few minutes of our attention. A little book, entitled "Chinese Medicine" has just appeared that packs into less than 200 pages the main points of the Chinese system of healing. And it is not done on the plan, either, of the man who wrote a book on Chinese philosophy by reading a book on China and a book on philosophy and combining the two. It is, in fact, written by the Dean of the Medical School of the West China Union University at Chengtu, in Szechwan Province, William R. Morse, M.D., L.L.D., F.A.C.S., and is published by Paul B. Hoeber in New York.

Imagine, if you can, the countless doctors, quacks, mountebanks, and what not in that vast land dosing the sick with powdered bones of monkeys, bears, and tigers, bats' wings, infants' brains, dragon's blood, bear's gall, earth worms, tree grubs, toad's skin, etc. Imagine itinerant doctors thrusting hot and cold needles, some of them eight or nine inches long, into various parts of the body to cure assorted ills. If the patient dies, it is the disease that kills him, of course, not the needle!

We must keep in mind, however, that the medical profession in China is not to be judged by the performances of the charlatans, any more than is the medical profession in this country. Any one who likes

can practice medicine there, so it is true that the land is overrun with medical fakers, but at the same time a body of serious and learned physicians exists, who have a system of medicine that has been in use for thousands of years.

The basic principles of this system are the Yang and Yin, or the masculine and feminine forces. The Yang is creative, the Yin destructive. Everything is classified under them. Heaven, the sun, day, life, heat, the spiritual, acid, the organs, energy, fever, etc., are Yang, while the earth, the moon, death, cold, the material, the base, the viscera, inertia, chill, etc., are Yin. This classification runs through thousands of objects, everything imaginable. The medical importance of it is that when the two principles are working in harmony, there is health; if not, there is illness, destruction, death. These two terms run back more than 4,000 years.

The next principle in the Chinese medical philosophy is that everything animate and inanimate is composed of five basic elements which were formed and are controlled by the Yang and the Yin, and that the proportions of the Yang and the Yin are constantly changing in a continual ebb and flow. This makes the task of the physician clear. If the patient is ill, he is lacking in Yang, or life-giving substance, therefore he should take something rich in Yang, such as cinnabar, gold, silver, jade, pine tree, peach, crane, cock, or tortoise. Cinnamon has great power. Legend relates that Chao, the hunchback, took cinnamon for twenty years, and hair grew on the bottom of his feet, he could walk 100 miles in a day and lift 1,333 pounds. Peach resin, too, steeped in the secretion of mulberry ashes, if eaten is reputed to cure all manner of diseases. "If eaten for a long time, one's body becomes buoyant and luminous. On a dark night the body will appear as the moon." Of course, just how desirable that would be is a question.

Air is held to be a vitalizing substance, and he who breathes expertly keeps away evil influences. Patients with colds or cold extremities are treated by having young boys and girls blow on their navels. Blowing on wounds stops bleeding, on the joints

it cures rheumatism and arthritis. The air is supposed to be "alive" from midnight to noon and "dead" from noon to midnight. Demons and devils bring disease, and tom-toms and firecrackers drive them away. If the patient dies during medical treatment, it is the disease that kills him, but if he dies after surgical treatment, the relatives hold that the doctor killed him, and their feelings can be assuaged only by large cash payments, hence surgery is rare in China.

The opinion is almost universal among the Chinese that all the doctor needs to do to diagnose any disease is to feel the pulse, and pulse interpretation, we are assured, is, in fact, *"the foundation of practice of medicine by the better class of Chinese physicians."* The procedure is extremely delicate and complicated, and may take from ten minutes to three hours. Each wrist has six pulse locations, and each location shows three qualities of Yang and three of Yin, so there we have 72 subdivisions and differentiations to start with, and each one may reveal from eight to twelve varieties of pulse. The really skillful doctor, too, will allow for age, sex, temperament, weight, and growth of the patient, and not forget the time of day, season of the year, influence of the stars, date of birth, and all other related considerations.

With all these in mind, then, the physician may find the various twelve pulses buoyant, sinking, feeble, bounding, fragmentary, continuous, fatal, slippery, small, empty, hollow, taut, hard, wiry, soft, scattering, slender, hidden, tremulous, running, intermittent, and irregular. These are only a few. There are said to be at least 51 chief types of pulse recognized as a groundwork in examination. Twenty-seven indicate a fatal ending of the disease.

It is easy to find material for ridicule in all this, of course, but Dr. Morse, who knows the Chinese doctors well and has lived among them many years, testifies that not a few are real masters of medicine. They seem to have "an intuition akin to the knowledge of the 'old salts' in their grasp of weather conditions." Many of the remedies, perhaps, are useless and

nauseating, "but many are very useful and have been used for centuries for the same diseases and in somewhat similar manner as they have been and are used in the West." Take toad skins, for example, which are used for dropsy. An analysis of toads' skins has shown they possess a digitalis-like substance, so that in this and many other Chinese medications, Dr. Morse notes, it is shown that their empiricism discovered and used substances which scientific investigation in Western laboratories now accepts as having a scientific basis.

Whether we can learn anything useful from their system of medicine is open to grave doubt, but in glancing through the pages of this entertaining and scholarly volume one notes that Shen Nung, one of the Chinese gods of medicine, who lived in 2767-2687 BC, "is said to have had the power of looking through his anterior abdominal wall and viewing the action of his stomach. He utilized this ability in watching the action of drugs he had eaten." If Shen Nung could be induced to return to earth, his services at least might be of considerable service.

The Craze for Regimentation

The mania for black shirts, brown shirts, red shirts, blue shirts, and gray shirts here and there around the world seems to some observers to be a symptom of a wide trend toward regimentation, a timid surrender of individuality and independence, and a retreat into the refuge of mass action under the authority and command of some leader or dictator.

The threatened move toward socialized medicine is part and parcel of this general urge to organize and regiment everybody. One medical writer calls it "guinea-pig-omania," in which we are all guinea-pigs under experimentation.

Independence is going out of style; the old freedom of personal action which produced the fine relationship between doctor and patient is in danger of becoming only a memory.

We see throughout the world, in fact, what looks like a revolt against freedom, a widespread distrust of liberty, due not to a

love of discipline but to a sheer failure of nerve, a lack of self-confidence. That is how it appears to a British historian, Mr. John Buchan. He sees "an impulse to huddle together and to seek salvation in herds, a fear of being alone, a craving to surrender the will to any authority which will save trouble." It is a symptom of the depression, which has produced a defeatist psychology. The danger is that this spirit may lead us into a regimentation of many features of our national life, including medicine, just as the depression is ending, and we shall emerge into better times saddled with this incubus which is totally foreign to the American character and to all that has made our country the admiration and envy of the world.

If there is any one thing that marks America out as distinct and different from other lands, it is the spirit of personal independence. Our country was founded in that spirit in the days of the Boston Tea Party and it has continued in that spirit down to the present time. Immigrants coming to our shores in millions declare that they come because "America is a free country." In their old home lands the people are herded and regimented until even to day in some countries of boasted civilization and culture the citizen does not dare breathe a word of criticism of the dictator who cracks the whip over the heads of the people. Our national songs celebrate America as the land of the free. Is it possible that just because we have experienced a business slump, we are willing to throw all this overboard and imitate the herded and regimented peoples of the Old World? And even if we do not go to the lengths that some of them have gone, are we going to regiment the medical profession and have them running here and there at the word of some political appointee who lands the job of bossing the state or city health-machine?

For our part, we believe that the spirit of freedom in America still lives. Our land is filled from the Atlantic to the Pacific with the sons and daughters of those who came here to escape the regimentation that was and is the curse of the old lands now showing signs of decay. That

a nation of such ancestry should deliberately saddle itself with this handicap is unthinkable. And those who are trying to bring it about can succeed only if the rest of us sit idly by in a mood of defeatism and let them do it. No profession in America has more influence and commands more respect than the medical profession, and a united stand at this time for old-fashioned American independence will defeat this new peril to our liberties.

District Branch Meetings

The date schedule for the Annual Meetings of the District Branches has been compiled as follows:

- First District—October 24—place to be announced later
- Second District—November 15—Garden City Hotel
- Third District—September 19—Potts Memorial Hospital (eight miles south of Hudson on the Albany-New York Post Road)
- Fourth District—September 21-22—Gloversville
- Fifth District—October 2—Syracuse
- Sixth District—September 26—Cortland
- Seventh District—September 27—Auburn
- Eighth District—October 4—Jamestown

The JOURNAL urges all members to attend the meetings of their own District Branches.

AMERICAN CONGRESS OF PHYSICAL THERAPY

The Thirteenth Annual Scientific and Clinical Session will convene at the Bellevue Stratford Philadelphia, September 10, 11, 12, 13, 1934. On the evening of September 12 a joint meeting will be held with the Philadelphia County Medical Society. Information may be secured from the President of the Eastern Section, Dr. John D. Currence, Hotel New Yorker, New York City, or the Secretary, Dr. Madge C. L. McGuiness, 1211 Madison Avenue, New York City.

Only 7 deaths occurred among the obstetrical patients during the past year at the Lying-In Hospital in New York City, according to its 135th annual report made public in July through the United Hospital Fund. The report disclosed a new high record in the number of mothers and babies cared for in the institution. Last year the hospital treated 4,387 obstetrical patients in its indoor and home delivery services and 626 gynecological patients, a total of 5,013. The 7 deaths among the obstetrical patients during the year made the maternal mortality rate 1.9 per 1,000 live births compared with 3.3 the previous year and 5.98 for the entire city in 1932. The infant mortality during the first two weeks following birth was 3.86 per 1,000.

Books

BOOKS REVIEWED

The Practical Medicine Series.—Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Series, 1933. Chicago, The Year Book Publishers [c. Series, 1933]. The 1933 Year Book of Obstetrics and Gynecology. Edited by Joseph B. DeLee, M.D. 12mo. of 630 pages, illustrated. Cloth, \$2.50.

This is a comprehensive review of the year's gynecological and obstetrical literature. The subject matter is well arranged and briefly but sufficiently presented. What is new in this special field may be determined by a perusal of its pages. The editors have added much valuable information with their terse comments. Some revolutionary ideas are brought to the reader's notice, but overenthusiasm of those in favor of such ideas is curtailed by sane editorial notations. This is an invaluable addition to the specialist's library and a book that every practitioner should read.

Wm. C. MEAGHER

Bright's Disease.—A Clinical Handbook for Practitioners and Senior Students. By J. Norman Cruickshank, Octavo of 208 pages. Baltimore, William Wood & Company, 1933. Cloth, \$3.75.

This volume is the last word on the nature and recent progress made in the study of Bright's disease. It is written in a clear and practical fashion, so typical of the English writers. The functions of the kidney with the Volhard and Fahr classification of Bright's disease are discussed. Other classifications of Bright's disease as well as tests for renal functions are presented in the appendix. A chapter well worth study is that devoted to edema in which the mechanism and various theories of edema are presented. A chapter is devoted to the therapy of the various types of Bright's disease. In the appendix the microscopic anatomy of the kidney is clearly presented. The practitioner's time devoted to the study of this volume will have been profitably spent.

HENRY JOACHIM

Treatment in General Practice.—By Harry Beckman, M.D. Second Edition. Octavo of 889 pages. Philadelphia. W. B. Saunders Company, 1934. Cloth, \$10.00.

The demand for a second edition of this valuable book on treatment demonstrates the value of this subject and its presentation in the practice of medicine. There is no doubt that the treatment of disease is a subject somewhat neglected in the curriculum of the medical college. This volume presents the subject concisely, accurately and as simply as possible. The preparation of the second edition has given the author the opportunity to omit some of the less important matter in the first edition, and to add newer subjects not covered in the earlier edition. This book would be valuable in the reference library of every physician. It is well written, clearly printed on the finest paper and is an excellent example of the publisher's handiwork.

HENRY M. MOSES

The Practical Medicine Series.—Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Series 1933, Chicago, The Year Book Publishers [c. 1933]. The 1933 Year Book of Pediatrics, edited by Isaac A. Abt, M.D., and Arthur F. Abt, M.D. 12mo. of 548 pages, illustrated. Cloth, \$2.25.

The year book of pediatrics for 1933 is a larger volume than usual. The contributions to pediatric literature are constantly growing so much that it is a problem even for the specialist to keep up with developments in this field.

The authors have therefore performed for us a distinct service in compiling such an interesting volume, in which the world's literature has been so carefully reviewed. The volume is certain to receive a cordial welcome, and it may very well be recommended as an index of the progress in the field it covers for the year of 1933.

JOSEPH C. REGAN

Food and the Principles of Dietetics.—Seventh Edition. By Robert Hutchinson, M.D., and V. H. Mottram, M.A. Octavo of 630 pages. Baltimore, William Wood & Company, 1933. Cloth, \$7.25.

Of all books on dietetics, it is the opinion of the reviewer that this one is probably the most complete. It has justifiably gone through seven editions, having first appeared in 1900. Everything concerning present knowledge of food appears in this book, well classified and well described. In presenting every food that the civilized race utilizes, the author describes the physical properties of the foodstuff, its digestibility, chemical

ingredients, method of preparation, economic value, and place in the diet. It contains an excellent chapter on spices and condiments. There are interesting chapters on the various alcoholic beverages, their chapters on the various alcoholic beverages, their value in diet. A method of preparation and their value in diet. A portion of the book is devoted to feeding in health, which includes feeding in infancy and childhood. Another small portion is concerned with feeding in disease.

W. S. COLLENS

The Practical Medicine Series.—Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Series, 1933. Chicago, The Year Book Publishers [c. 1933]. The 1933 Year Book of Urology, Edited by John H. Cunningham, M.D. 12mo. of 445 pages, illustrated. Cloth, \$2.25.

This book gives the best résumé of the year's progress and practice in urology of any piece of literature that we have seen. Its supreme value is due to the balanced judgment of the editor. The selection of what articles to print, the presentation of the meat of the paper and the editorial comments, with references to other articles in the Year Book Series, are of a high critical acumen and could only have been done by a fine intelligence joined with a master urologist's practical experience. Many papers will be of interest to all practitioners while the special worker in the field of urology will find no article without interest and of his great practical value in estimating the worth of his present procedures or suggesting new ones. No current urological file is complete without this book.

STURDIVANT READ

Laboratory Medicine.—A Guide for Students and Practitioners. By Daniel Nicholson, M.D. Second Edition. Octavo of 506 pages, illustrated. Philadelphia, Lea & Febiger, 1934. Cloth, \$6.50.

This book is intended chiefly for the use of practitioners of medicine. It is one of the most practical books we have seen and is crammed with information. Chapter I deals with the clinical indications for laboratory tests. Chapter II gives the technique of getting blood. Subsequent chapters deal with hematology blood chemistry, immunity reactions, exudates, sputum, spinal fluid, gastric, duodenal, and intestinal contents, and urine. The last chapter outlines laboratory equipment for physicians. The interpretation of the tests is particularly good. A wealth of information is to be found between the covers of the latest revision of this work.

E. B. SMITH

Contagious Diseases.—What They Are and How to Deal with Them. By W. W. Bauer, M.D. 12mo. of 218 pages. New York, Alfred A. Knopf, 1934. Cloth, \$2.00.

This well-written and interesting little book fulfills a distinct need as medical books on contagious diseases designed for lay reading are comparatively rare.

The chapter dealing with quarantine could be read to advantage by most physicians. Another chapter dealing with the selection of a proper sick-room and preparation for its use, is excellent. This chapter also lists all utensils needed for the care of a contagious case.

Other chapters deal with the symptoms of common contagious diseases and parasitic infestations.

All through the book the author has stressed the necessity for calling a physician to make a diagnosis and institute treatment and has been scrupulously careful not to encourage unsupervised home treatment. He urges hospitalization as the ideal method for handling contagion.

H. L. BARNES

Nature, M.D.—Healing Forces of Heat, Water, Light, Electricity and Exercise. By Richard Kovacs, M.D. 12mo. of 181 pages, illustrated. New York, D. Appleton-Century Company, 1934. Cloth, \$2.00.

Dr. Kovacs has compressed into a small volume a fund of information which only a whole library could cover in detail. While reading this book the reasons become clear why physical therapy is and should remain a part of medical practice. The error of its delegation entirely to lay workers is apparent. Though written for lay information the book can be read to great advantage by the medical student and practitioner. It is well written, clearly printed, and adequately, though amusingly, illustrated. The book deserves a place in every public and home library, and the writer is to be commended upon the thought behind the work as well as its delightful presentation.

JEROME WEISS

A PATHOLOGICAL STUDY OF THE "STRAWBERRY" GALLBLADDER

H HAMILTON COOKE MD

Boston Mass

*Formerly Fellow in Surgery The Mayo Foundation Rochester Minnesota**This essay was awarded the Merit H Cash prize of the Medical Society of the State of New York on April 4 1933*

The recent outstanding additions to our knowledge of the structure, function, and pathology of the gallbladder have been of great value in the clinical interpretation and rational surgical management of cholecystic disease. The widespread use of cholecystectomy has provided an opportunity for the pathologist and surgeon to observe a large variety of lesions formerly seen only at necropsy. The minute study of numerous fresh surgical specimens, moreover, has made it possible to extend observations from terminal anatomic changes, to histologic structural changes produced by, or associated with, anomalies, infections, metabolic dysfunction, neoplasms, and stones.

Many conditions have been regarded as partially or completely responsible for the deposit of lipoidal material in the mucosa of the gallbladder. Virchow,⁹ in 1857, described microscopic deposits of lipoidal material in the gallbladder. He believed that lipoids were absorbed in the gallbladder by a physiologic mechanism identical with that by which fats are absorbed in the small intestine. Aschoff, in 1906, after a number of experiments, concluded that cholesterol in the wall of the gallbladder is absorbed from the bile in a mixture of neutral fat. Moynihan, in 1909, presented a macroscopic description of lipoidal deposits in the mucosa of the gallbladder. MacCarty,¹⁴ in 1910, published the first detailed macroscopic and microscopic study of lipoidal deposits in the gallbladder. Irwin and MacCarty,¹⁰ in 1915, studied 85 fresh specimens of papilloma of the gallbladder that were found on examination of 2,165 gallbladders removed for cholecystic disease. The papillomas were yellow or white and appeared to be like hypertrophied villi. In the stroma were found numerous large, round or oval cells

which contained fat or a fat like substance. MacCarty observed macroscopic lipoidal deposits in 936 (18 per cent) of 5 000 gallbladders removed at operations, later, he studied the early lesions in 4,998 gallbladders. Infiltration of the epithelial cells by lipoidal globules and the presence in the submucosa of large spheroidal cells filled with finely granular lipoidal material was considered to be one of the early lesions of the gallbladder. Boyd,⁵ in 1923, studied 100 gallbladders removed because of cholecystic disease. The mucosa of the "strawberry" gallbladder was found by chemical examination to contain as much as 100 times more cholesterol than the mucosa of the normal gallbladder. Mentzer,¹⁷ in 1925, studied 134 strawberry gallbladders which were found at 633 consecutive necropsies. He found that the majority of persons with fatty changes in the wall of the gallbladder also had fatty changes in other parts of the body. Judd and Mentzer,¹¹ in 1927, studied the clinical history of 500 patients with cholesterosis and 500 patients with cholesterosis associated with cholelithiasis. In 200 cases of cholesterosis, the cholesterol content of the blood was determined by repeated examinations, an appreciable increase over the normal standards was found in each case.

The material used in this study was composed of 585 strawberry gallbladders among which were 85 fresh specimens. Each specimen was examined grossly and microscopically. Frozen sections were stained by polychrome methylene blue, hematoxylin eosin, sudan IV, scarlet red, Nile blue sulphate, and silver carbonate. Paraffin sections were examined by hematoxylin-eosin, Weigart's, van Gieson's, and mucocarmine stains. Frozen sections were studied with the polarizing microscope. Microchemical tests for lipoids were made

according to the technic of Strzyzowski and Boyd. Determinations of cholesterol were made by the technic of Salkowsky and Moleschotts.

Macroscopic examination of the 500 specimens of strawberry gallbladder revealed marked variation in the quantity of visible lipoidal material in the mucosa. The entire number was divided into three groups according to the amount of lipoidal material. Group 1 contained the smallest, Group 3 the largest, and Group 2 an intermediate quantity of lipoid. On the basis of this classification, 332 specimens were placed in Group 1, or slight strawberry gallbladders; 76 specimens in Group 2, or moderate strawberry gallbladders, and 92 specimens in Group 3, or marked strawberry gallbladders.

Fig. 1.—Marked strawberry gallbladder.

The only lipoidal material visible in several specimens in Group 1 consisted of a few isolated pinhead granules along the ridges of the tallest folds. In Group 3 most specimens, on the contrary, contained large quantities of lipoidal material, usually uniformly distributed over the entire surface of the mucosa. The lipoidal material in these specimens occupied not only every ridge of the tall primary and secondary folds, but also formed knob-like solid or pedunculated projections at the juncture of the folds. Definite papillomas were present in all three groups but were larger and more numerous in the specimens of marked strawberry gallbladder. The lipoidal material stopped abruptly at the juncture of the gallbladder with the cystic duct and was not observed in the cystic duct.

There is no unusual structural change in the appearance of the folds free from lipoidal material in the specimens in which the lipid is confined to a portion of the mucosa. The accumulation of the lipoidal

material in the folds of the mucosa produces definite changes which vary in degree according to the quantity of lipoidal material and the extent of associated pathologic changes. The folds do not retain their tall, thin, tenuous structures, but become bulbous, flask-shaped, mushroom-shaped, and, in the marked examples, the base of the fold becomes transformed into a thin pedicle whereas the free portion on cross section has an expanded balloon-shaped appearance. The wall may vary from normal thickness to the massive hypertrophy seen only in cases of advanced gangrenous or fibrous cholecystitis.

The histologic appearance of sections from specimens of strawberry gallbladders may vary markedly. The variations are principally dependent on the quantity of lipoidal material present in the mucosa and the degree of associated pathologic changes in the different layers of the wall. Marked structural variations may be present in sections from various portions of the same specimen and, occasionally, even in different areas of the same section. The main portion of the lipoidal material is always found in the folds of the mucosa. Small quantities are occasionally present in the deeper portions of the mucosa that lie between the base of the crypts and the inner portion of the muscular layer. Lipoidal material in the tunica fibrosa externa is rare and, when present, is found in the cytoplasm of macrophages that apparently have migrated from the interstitial portions of the folds.

The lipoidal material in the epithelial cells is almost always found in the distal portion of the cells. In sections stained by scarlet red it is visible as a pink to dark-red globular material. The quantity contained in the epithelial cells varies considerably. In some cells only a few globules are seen, whereas in others the cytoplasm distal to the nucleus is so distended by a coalescent foamy mass that, in extreme cases, the cells may assume a goblet shape. In sections stained by Nile blue sulphate, the subepithelial lipoidal material took various shades of color. Most of the coalescent lipoidal material appeared as dark-blue and globular, whereas the smaller, more diffusely distributed masses took a bright-blue or azure stain.

The largest quantity of lipoidal material in the strawberry gallbladder is found in the cytoplasm of large, peculiar mononuclear cells that are situated in the stroma of the folds. Some villi contain only a few

of these cells, whereas in others the lipid-containing cells are so numerous that they compose the entire interior portion. In the latter condition the epithelial cells rest directly on the lipid cell. The size of the mononuclear lipid cell varies according to the quantity of lipid in the cytoplasm. These cells usually measure from 20 to 60 microns in diameter; they are usually rounded, oval, or slightly angular but may assume different shapes depending on the structure of the fold and the degree of associated inflammatory changes. The cytoplasm appears foamy, as if it were composed of numerous small globules. The nucleus is often covered or obscured by the globular material. The nucleus, which is small and rounded, may be situated near the center of the cell, but it is usually found about midway between the center and the periphery.

On examination with the polarizing microscope the intercellular lipoidal material exhibited marked anisotropic reaction. This reaction appears to be so definite that if an unstained section presented marked anisotropic reaction, subsequent histologic examination revealed numerous lipid-containing macrophages in the stroma of the villi. No lipoidal material was detected in the cytoplasm of any fibroblasts, fibrocytes, leukocytes, lymphocytes, plasma cells, or endothelial cells that lined the lumens of the arteries, veins, and capillaries. Extracellular or intracellular anisotropic material was rarely observed in the deep portions of the muscular layer or in the tunica fibrosa externa. When present, it was associated with such advanced structural changes in the muscular layer as those that marked separation of the muscle fibers of deep crypts and diverticula.

Macroscopic quantities of lipoidal material in the mucosa of the gallbladder may be associated with various degrees of structural changes. These structural changes are confined almost exclusively to the mucosa and consist primarily of change in the size, shape, and color of the folds. Although lipoidal deposits are observed in the mucosa of specimens of acute gangrenous cholecystitis with or without cholelithiasis as well as in gallbladders with thick fibrous walls, they are most commonly found associated with the condition described as chronic catarrhal cholecystitis.

On comparing numerous sections from specimens of slight and marked strawberry gallbladder it was observed that certain of the structural changes were present so

uniformly that they merited special study as the basis for histopathologic elucidation and possible explanation of this condition. The changes were: alterations in the structure at the base of the folds, alterations in the muscular layer, the presence of lipoidal material in the lymph spaces, and cellular reaction to the lipoidal material free in the stroma of the folds. In almost all specimens of lipoidal deposit in the gallbladder, more or less marked structural changes were present in the muscular layer. The bundles of muscle fibers which composed the inner border of the muscular tunic were displaced in an irregular manner. By this change the muscle fibers were

Fig 2—Large quantities of lipid in the folds of the mucosa (x 10).

frequently pushed inward to occupy the base of the folds. In some specimens the bundles of muscle fibers were not only present in the base of the folds but extended like a wedge into the deeper portions of the stroma. Variable quantities of lipoidal material were found in the apical portion of the folds which revealed this abnormal appearance at the base. The presence of bundles of muscular tissue appeared to act as a block to the dissemination of lipoidal material from the apical portion to the basal portions of the villus. The distribution of the lipoidal material appeared to be entirely limited by the presence of the muscle tissue.

The presence of macroscopic quantities of lipoidal material in the mucosa of the gallbladder could not be predicted by any criterion from examination of the exterior appearance of 85 fresh specimens of strawberry gallbladder. The color of the serosal surface of the gallbladders in this group varied from almost normal to such extremes as the dull grayish-white usually present in fibrous cholecystitis or the congested hemorrhagic discolorations of gangrenous cholecystitis. On palpation the

wall of an occasional specimen of strawberry gallbladder appeared to possess all of its original smoothness, elasticity, and suppleness in contrast to other specimens that revealed the usual evidences of advanced acute or chronic inflammatory changes. The only basis for the detection, macroscopically, of quantities of lipoidal deposit in the mucosa is the direct inspection of the mucosa.

COMMENT

Macroscopic quantities of lipoidal material in the mucosa of the inflamed gallbladder present a striking appearance. It is therefore difficult to understand why this gross appearance of lipoidal deposits in the mucosa was not described until more than fifty years after the observation of microscopic quantities of lipoidal material in sections of the wall. Moynihan suggested that the yellow masses were really small stones embedded in the mucosa. MacCarty showed, however, that the yellow masses were composed of clumps of lipoidal material in the folds of the mucosa. The sharp contrast between the red hyperemic mucosa of the acutely inflamed gallbladder and the diffusely distributed yellow clumps of lipoidal material suggested to MacCarty the appearance of a ripe strawberry. He therefore designated this condition "strawberry" gallbladder. The lipoidal material in the strawberry gallbladder may vary considerably in quantity and in distribution. In 332 of 500 specimens examined in the course of this study, lipoidal deposits were confined principally to the apices of the taller folds. Large amounts of lipid were, however, present in the primary, secondary, and in some of the tertiary folds of 92 specimens of the same group. In most specimens of strawberry gallbladder the lipoidal material is not restricted to any particular portion of the mucosa. The distribution of the lipoidal material was diffuse in 444 of 500 specimens, whereas it was confined to the corpus, fundus, or cystic portion of the mucosa in 56 specimens.

The presence of lipoidal material ends abruptly at the juncture of the cystic duct with the gallbladder. Large quantities of lipoidal material frequently accumulate at the juncture of the taller folds. These areas vary in size and may appear as polypoid masses attached to the mucosa by a thin, fragile stalk. The polypi are bright yellow and vary considerably in size and shape. On section they are found to be

composed of a large number of large, mononuclear cells which are distended by numerous globules, or to be a single homogeneous mass of lipoidal material. The free portion of the polyp is usually surrounded by a single layer of tall epithelial cells similar to those that cover the folds of the mucosa. In some specimens of strawberry gallbladder the lipoidal material is distributed as small punctate masses without any evidence of polypoid formation, whereas in some specimens the larger portion of the lipoidal material appears localized in a few polypoid masses.

The gross appearance of the strawberry gallbladder depends to a great degree on the condition of the mucosa. In the acutely inflamed strawberry gallbladder the mucosa is thick, red, and hyperemic, whereas in some specimens of chronic cholecystitis with lipoidal deposit the mucosa appears almost normal, except for the presence of the yellow clumps of lipoids.

In sections of the strawberry gallbladder the lipoidal material can be demonstrated by such fat stains as scarlet red, osmic acid, Nile blue sulphate, and Sudan III. On gross examination of a marked specimen of strawberry gallbladder the lipoidal material appears to lie as irregular masses directly on the apices of the villi. This is, however, not the case. The lipoidal material is found entirely within the villi and cannot be picked off or removed except by injuring the mucosa. In the mucosa, the lipoidal material is situated in the epithelial cells, free in the stroma, and in the cytoplasm of large peculiar cells. In occasional sections it is possible to find small numbers of free lipid globules and a few lipid-containing cells in the submucosa, but it is rare to find any lipid cells or free lipoidal material in the muscular layer or the tunica fibrosa externa. When gross lipoidal deposits are present in a particular portion of the mucosa, each epithelial cell usually contains lipid globules, but the amount of intracellular lipoids varies considerably. The cells nearest the apex of the tall primary folds always appear to contain the largest amount. The epithelial cells which line the tertiary folds and the crypts, contain relatively small amounts of demonstrable lipoidal material, even in marked specimens of strawberry gallbladders. Lipoidal material is, however, not present in all the epithelial cells of each fold in every portion of even the most advanced strawberry gallbladder.

Almost all of the intracellular lipoidal material is found in the cytoplasm of large peculiar mononuclear cells. These cells were first observed and described by Aschoff,³ and later studied in detail by MacCarty. The cells measure from 20 to 60 microns in diameter. The small, round or slightly indented nucleus is often situated near the periphery. The cells are usually round, but may be hexagonal or elongated to resemble a fibrocyte. The quantity of lipoidal material in the cytoplasm of these cells varies considerably. In some sections the cells contain only a few lipoid granules which can be detected only on minute examination. In other sections the entire cell is packed with cells distended by small globules or coalescent masses of lipoids. When the cytoplasm is distended by lipoidal material, it is frequently impossible to demonstrate the nucleus. If the lipid is dissolved by alcohol, the structure of the cells can, however, be observed and the nucleus identified. On the basis of this histologic appearance Aschoff called these cells "Schaumzellen" or "pseudoxanthoma" cells from their resemblance to cells which form xanthoma. The Schaumzellen possess a highly developed power of phagocytosis. Structurally and functionally they are phagocytic histiocytes. The size and appearance of this cell depend on the amount of lipoidal material accessible for incorporation into the cytoplasm. It is a well-known observation that the macrophages can resemble in shape and structure other cells present in connective tissue, such as fibrocytes and fibroblasts, and although in some instances the cells of the connective tissue may be difficult to distinguish by morphologic criteria, the macrophages can be identified by their ability to phagocytize foreign material. By taking advantage of this property, Kusnetzowsky¹² and Anitschkow¹ have studied the macrophages of the subcutaneous tissue, and I have demonstrated by experimental methods the presence of macrophages in the gallbladder of the dog.

The serosal surface of the strawberry gallbladder may vary considerably in appearance, and the frequency of occurrence of the various types of inflammatory changes in surgical specimens of strawberry gallbladder will vary somewhat according to the number of specimens examined. There is, however, little doubt, as originally pointed out by MacCarty that

lipoidal deposits are most commonly found in gallbladders that are the site of those inflammatory changes usually designated as chronic catarrhal cholecystitis. Lipoidal deposits can, however, be observed in the mucosa of the acutely inflamed gallbladder. In 500 consecutive surgical specimens of strawberry gallbladder, 21 revealed acute cholecystitis. The inflammatory and cellular infiltration present in the tunica muscularis, tunica fibrosa externa, tunica

Fig 3.—Histiocytes distended with lipid globules in the mucosa in cases of marked cholesterosis (x 1,000).

subserosa, and serosa of a strawberry gallbladder may vary from very slight to the most advanced.

The physical characteristics of the bile were observed in 85 surgical specimens of strawberry gallbladders. In a number of instances the bile had a thick, dark, tarry consistency. Many other gallbladders, however, contained bile of a normal color and consistency. The appearance of the bile did not vary with the amount of lipoidal deposits in the mucosa but was dependent on the degree of associated inflammatory changes in the wall. This apparently had not been noted by other observers.

The nature of the lipoidal material in the mucosa of the strawberry gallbladder has been investigated by histologic, chemical, and optic methods. The histologic methods have consisted of an interpretation of the color changes produced in sections of strawberry gallbladders stained with osmic acid, sudan III, scarlet red, or Nile blue sulphate. The quantity of cholesterol has been determined by a modification of the method used by Bloor for the analysis of the cholesterol content of the blood. The optic reactions of the lipoidal material have been examined by the polarizing microscope. Among in-

investigators of this problem it is almost uniformly conceded that the material in the mucosa of the strawberry gallbladder is not composed of a single substance but is a mixture of various fats, lipoids, and soaps. Aschoff,² Gosset,⁸ Policard, Boyd,⁵ Chiray,⁶ Lecene,¹³ Blaisdell,⁴ and Illingworth⁹ consider the material to be a loose mixture of soaps, neutral fat, fatty acids, cholesterol, and cholesterol esters. Great emphasis has naturally been placed on the part played by cholesterol and cholesterol esters in this condition. In this study numerous observations were made of the color reactions, chemical reactions, and optic properties of the lipoidal material in the mucosa. The lipoid globules in the epithelial cells consist of a mixture of neutral fat, fatty acids, and soaps. No cholesterol or cholesterol esters can be determined in the epithelial cells by histologic, chemical, or optic methods. The extracellular subepithelial accumulations of lipoidal material, however, contain considerable amounts of cholesterol and cholesterol esters. The pseudoxanthoma cells contain large amounts of cholesterol and cholesterol esters in their cytoplasm. Suggestions have been made by several writers that strawberry gallbladder is only local evidence of a condition existing throughout the biliary tract. No proof has been published to support this contention. On the other hand, it is enough to point out the sudden arrest of the lipoidal deposit at the juncture of the gallbladder with the cystic duct to emphasize that if a similar condition exists throughout the biliary duct system, it must be exceedingly rare. At necropsy carried out by me in several cases in which there was a marked strawberry gallbladder, no evidence was found of a similar condition in the extrahepatic and intrahepatic bile ducts.

SUMMARY

Strawberry gallbladder is a condition in which macroscopic lipoidal deposit is present in the mucosa of the gallbladder. In 500 consecutive surgical specimens of strawberry gallbladder the quantity of lipoidal material could be designated as slight in 332, moderate in 76, and large in 92. The lipoidal material was not uniformly restricted to any particular area of the mucosa. In the 500 specimens the lipoidal deposit was diffuse in 444 (68.8 per cent), whereas it was found in various

portions of the mucosa in 56 (10.0 per cent). The strawberry appearance of the mucosa may be associated with all degrees of acute, subacute, or chronic cholecystitis, except in conditions in which the mucosa is desquamated or replaced by scar tissue. In 437 of 500 consecutive surgical specimens of strawberry gallbladders, definite gross and inflammatory changes were found in the wall, whereas in the remaining 63 specimens similar but less advanced changes were observed on microscopic examination. The structural changes which may account for accumulation of lipoidal material in the mucosa are: various degrees of fibrosis at the base of the villi and in the submucosa, accumulations of cholesterol-containing lipoids in plaque-like areas which resemble cross sections of lymphatic vessels, and the phagocytic reaction of local histiocytes to the presence of large quantities of free lipoids.

THE TREATMENT OF OBESITY

JOHN McCABE M D and JAMES FINLAY HART M D

New York City

There is considerable confusion about the treatment of obesity. This is due in part, to the generally accepted view that obesity develops from different causes and in part to the number of different methods employed in reducing weight. Furthermore practically all impressions regarding the value of any one treatment are gained from observations on ambulatory cases. However, when it is possible to put the subjects under scientific supervision with complete control over a sufficient length of time, the situation clarifies itself and the treatment of obesity becomes very simple. It then becomes apparent that the treatment is primarily dietetic irrespective of the etiology.

In this communication the authors will make a critical analysis of the common methods of treating obesity, emphasizing the low calorie diets as proposed by Evans and Strang¹ and finally present their experience with these methods and the conclusions that they have drawn therefrom.

OBJECTIVES IN THE TREATMENT—Three objectives in the treatment of the obese can be distinguished. The excess weight which has piled up must be removed, any coexisting abnormality should receive due consideration and should be treated along approved lines, and when the normal weight has been attained a plan of procedure must be outlined lest the condition reoccur.

REDUCTION OF OVERWEIGHT THE MAIN OBJECTIVE—The first objective in the treatment of the obese is to remove the overweight. It may seem a platitude, but the paramount object in the treatment of obesity is the reduction of weight. It must not be lost sight of that excess weight is the chief complaint of all but a few of the obese, and that the adiposity is the outstanding symptom whether it acts as a burden to carry, or imposes an embarrassment on myocardial function or becomes detrimental to the appearance, or provokes a fear of future complications. And so it follows that some means of reducing this surplus should be the main consideration in the therapy.

NATURE OF SURPLUS—It is generally conceded that the excess weight in the obese is fat with a small proportion of water. As far as known, excluding surgery, there is no way to get rid of body fat except by oxidation. And furthermore, excess fat, being a storage material, will not be oxidized unless there is a shortage of foodstuffs ingested. To reduce the overweight of the body there must be a discrepancy between the food intake and the needs of the body. The discrepancy can be brought about in two ways either the body needs can be raised or the food intake can be curtailed.

METHODS OF RAISING THE METABOLIC RATE

Before considering the raising of the energy output, it is necessary to look over the metabolic rates of the obese. Investigators agree that it is rare to find a basal metabolism in these cases below the normal. Kenyon² found 8 out of 50 with a —15 or below. Her figures are somewhat higher than the majority of writers have given. Evans and Strang have pointed out that the basal metabolism of the obese really runs around +20 or +25. They show that as the extra weight is inert fat and does not enter into the active metabolism of the body, it should be disregarded when making the estimation. Computing from "ideal" weight, then, it becomes apparent that the obese live at a dangerously high metabolic rate. Therefore, it would not be justifiable to increase this high metabolic rate by exercise or stimulants, but instead methods for lowering it should be employed.

MUSCULAR ACTIVITY—The first method usually employed in raising the metabolic demands of the body is to increase muscular activity. It is possible for one doing light work and using about 2,300 calories a day to take on extra heavy work and raise his body needs to 4,500 calories. In other words, it is possible to double the body's daily needs by exercise. Thus, if continued for any length of time, with the original food intake, would be of definite value in reducing weight.

HIGH PROTEIN DIETS.—The protein of the diet has a high specific dynamic action. According to Rubner,³ in a high protein diet the metabolism of the body may be raised 30 per cent above normal. The fats and the carbohydrates, on the other hand, under the same conditions, burn up only 12.7 and 5.8 per cent, respectively. The feeding of a high protein diet to the obese, therefore, might meet the requirements of the appetite but at the same time increases body metabolism 30 per cent. For instance, one on a 2,900 calorie diet of this type would burn up about 900 extra calories a day.

This might seem an ideal method of reducing but on close inspection one cannot but recognize limitations. First, there is a maximum amount of protein a human being can ingest. It is easily seen that an average individual eating 2,900 calories of food a day could not take it all in protein. Meat, for instance, having the highest content of protein of all our foods could scarcely be taken in amounts of over a pound and a half a day for any length of time. This amount contains much less than the required 2,900 calories. The protein content of this quantity of meat averages 180 gm. and its caloric value is 720. With the addition of other high protein foods it might be possible to raise the protein as high as 250 gm.

Since 250 gm. of protein is about the limit of human intake, it should give the highest value possible from the specific dynamic action. This amount, then, according to Rubner's figures would raise the metabolism enough to burn up 309 extra calories.

It must also be taken into consideration that in all protein foods there is considerable fat and sometimes carbohydrate, which are ordinarily inseparable from the protein. These bring the calories up but also in themselves have specific dynamic action.

The high protein diets as published in medical literature have run less than 175 gm. of protein. But they have all been, in truth, low calorie diets. This is shown by the first and most interesting obesity diet published, the Banting diet. This contains about 15 ounces of lean meat with additional proteins that bring the total up to 172 gm. The caloric value of the whole diet is 1,200, which is 1,700 calories less than the generally accepted normal intake. This difference alone could, if continued on with normal activities, cause

the loss of 2¾ lb. a week. The 172 gm. of protein, on the other hand, according to Rubner would cost the body only 212 calories. So the total reduction of the diet would eliminate 1,700 calories while the specific dynamic action of the protein would account for only 212 calories. Notwithstanding that both factors were operating, Banting only lost 35 lb. in ten months. This was less than 1 lb. a week.

TABLE I.—COMPARISON OF SOME WELL-KNOWN OBESITY DIETS*

	Carbo- hydrates, gm.	Protein, gm.	Fat, gm.	Total calories
Normal diet.....	400	100	100	2900
Epstein.....	50	100	85	1400
Banting.....	81	172	8	1100
Hirshfeld:				
Maximum....	122	134	46	1500
Minimum.....	106	95	43	1220
Oertel:				
Maximum....	120	170	45	1608
Minimum.....	75	156	25	1180
Robin.....	82	140	44	1200
Von Noorden....	112	155	28	1366
Evans and Strang	36	60	10	474

* Adapted from Forchheimer

TABLE II

Example of a high protein diet, consisting of the highest protein foods available, and being the extreme protein intake of a normal human being doing average physical exercise. The high fat content of such a diet should be noted

	Carbo- hydrates, gm.	Protein, gm.	Fat, gm.	Total calories
Meat: 24 oz. 720 gm.	0	180	145	2025
Butter- milk: 32 oz. 1000 c.c.	48	30	5	320
Eggs: 2	0	12	12	156
Cheese, 3.3 oz. Amer: 100 gm.	0	26.4	33	409
Total	48	248.4	195	2910

It might be said, therefore, that the high protein diet gets most of its value from the fact that it is low in calories. And if one depends on the high protein without reduction of calories, it would be of value only to the mild or moderate type of obesity and of no practical value to extreme types that go to 300 lb.

Thyroid Extract.—Further, thyroid extract is a definite means of raising the metabolic rate. When the basal metabolism is below normal, thyroid extract should be used because of the hypothyroidism and there is no other known specific treatment. When it comes to the case of a patient with a normal, or, as has been shown in the obese, a high basal metabolism, conditions are different. In these cases the body is not short of thyroid. No justification exists for using this stimulant in a case

that registers a +25 metabolism. It would be like lashing a tired horse. As the great majority of cases have over a plus 15 metabolism the use of thyroid is limited to a small number of cases that actually show normal metabolic rates. Small doses given in these cases that do not show definite signs of hypothyroidism, simply give a tonic or euphoric effect. When large doses are given in the normal, definite results are achieved. Weight drops quite quickly for the first two weeks, but at about this time practically every patient develops thyrotoxic symptoms. Palpitation and general weakness appear and are only relieved by discontinuing the thyroid. Such symptoms are well known to every one who has tried to reduce weight by thyroid. It is also common experience that many patients actually gain weight while under thyroid exhibition.

Before a final estimate of the value of thyroid extract is made in any case, one thing must be taken into consideration. When patients are given thyroid they are put on a restricted diet. Whether they do or do not adhere to this diet will be of great importance. It has been the experience of the authors that those who did not pay attention to the diet either remained at the same weight or gained, while those that were exacting as to diet made definite losses. Thyroid extract may, in the opinion of the authors, be given credit, at times, for work done by dieting.

Dinitrophenol.—A new drug, dinitrophenol, has been proposed by Cutting⁴ as a stimulator of metabolism. As this is known to be a definite poison to the system, it would appear to be dangerous for general use, at least until considerable animal experimentation shall have been carried out.

It is possible, then, to raise the metabolic rate of the body by a number of methods. Two of these methods, increased exercise and raising the protein, are physiological when kept within certain bounds. The other two methods are artificial and toxic under certain conditions. Any attempt at raising metabolism in the obese, however, is dangerous because these patients live really at a high metabolic rate.

LOWERING THE FOOD INTAKE

Total Calories.—In lowering the food intake there are some generally accepted principles which should be observed. The total calories can be brought down to a

certain minimum, below which known and measurable metabolic imbalances will occur. The lowest scientific minimum so far proposed is that of Evans and Strang who in 1931 showed that diets as low as 400 calories were safe.

Individual Constituents.—To lower the total calories, consideration must be given to the individual constituents of the diet. It is customary to start with the proteins. Below a certain number of grams of protein a day, the body will draw on its own protein and so dissolve essential body structure such as muscles and vital organs. This can be shown by the nitrogen excretion in the urine. The minimum figure is usually put at one gram of protein for each kilogram of ideal weight. For example, a subject 5 ft. 5 in. has an ideal weight of 135 lb. and requires 61 gm. of protein, even though his actual weight may be 300 lb.

The carbohydrate, the largest item of the normal diet and the first call for energy and heat, has a minimum for the daily intake. It is generally felt, at the present time, that the glycogen stores of the body must not be lowered beyond a certain amount, and considerable literature has been published in recent years stressing this point. Various authors have shown from clinical and experimental evidence that the glycogen in the liver and the muscles acts as an integral part of the body metabolism as much or even more than it does as a simple storage of excess carbohydrate. They have shown that the glycogen acts as a buffer or a first-line trench against toxins; that its presence guarantees sufficient glucose to preserve the correct ketogenic-antiketogenic ratio so that fats will not produce acidosis; and also that it functions as a protein sparer. The figure of 100 gm. of glucose has been mentioned by a number of writers as a minimum daily intake that will be safe for the average person. According to Evans and Strang, this figure can be safely lowered in the treatment of the obese. In their studies they found that the ketogenic-antiketogenic ratio was of little importance because of low fats in the diet, but that there was a definite minimum carbohydrate below which abnormal protein metabolism occurred. From long periods of observation they concluded that 0.6 gm. of carbohydrate per kilogram of ideal body weight was required to spare the protein.

To remove all the fats from the diet is a physical impossibility. Evans and Strang could not go below 9 gm. a day. This amount represented the inseparable fat of the protein in the diets.

The diet then, for a subject 5 ft. 5 in. in height and having an ideal weight of 135 lb. would be protein 61 gm., carbohydrate 36.6 gm. and fat 10 gm., making a total caloric value of 480.

If this diet is to be observed for a considerable period of time, care must be taken that adequate minerals and vitamins be ingested. The 5 per cent vegetables which are plentiful in the diet will probably cover the body needs for minerals, but a glass of skimmed milk once a day will allow a definite surplus. The vitamins in such a low diet fall below normal needs. This is especially so of the fat-soluble A. Haliver oil, one capsule three times a day, will supply this shortage. The vitamin B efficiency can be brought up by adding one yeast cake or two tablespoonfuls of wheat germ a day. The vitamin D can be taken care of by the use of ten drops of viosterol each day.

The food intake, then, can safely be reduced to 400 or 500 gm.; 1,200 or more grams below the basal rate of over 2,000 calories under the average daily intake. Assuming the fat in the body to have the same caloric value as exogenous fat, 4 calories per gram or about 4,300 calories per pound, one could expect, with other factors being equal, a loss of from 3 to 4 lb. a week under this regimen.

RÔLE OF WATER IN BODY WEIGHT

There is a certain amount of water in the body which can be removed comparatively easily. Part of this is free and part is in combination with the fat. This water content may be lowered by several methods. The first procedure is to restrict the intake to about 1,000 c.c. a day. This will lower the weight a number of pounds in a few days. Thereupon a balance will be effected and no more weight will be dropped. The use of salt-free or low salt diets releases more of the body fluid, but likewise a balance is struck after a few days and no more weight is lost.

Sweating, as practiced by fighters and jockeys for reducing weight removes, at times, as much as 7 or 8 lb. at one sitting. This is only a temporary loss as the weight is regained when the usual quantities of water are again taken. This practice also

has a bad effect of washing out the salts of the body. The use of salyrgan in the treatment of the obese has recently been reported. This likewise removes the water of the body without attacking the fat and is in the same class as sweating as far as the return is concerned.

Large amounts of water can be removed by cathartics which in addition sweep the food out of the intestinal tract before it is absorbed. Hence, noticeable weight reduction can be made by lowering the water content of the body but the amount is limited to a small proportion of the total excess weight and is quickly regained when normal amounts of water are ingested. The excess fat, the greatest factor in obesity, is not disturbed.

SECOND OBJECTIVE IN TREATMENT

The next objective in importance is treatment of any coexisting abnormality according to the usual procedures for such cases. Adjustments in the obesity treatment can be made to conform with the treatment for the complication. If there is a cardiac, a nephritic or some other lesion present treatment thereof must be instituted along approved lines. In the same category should be placed endocrine dysfunctions. Where there is a frank endocrine disturbance present, which is amenable to treatment, such treatment should be instituted. Patients with minus basal metabolism should have the rate brought up to normal with thyroid; one with a pituitary adenoma may need an operation, and one with an ovarian dysfunction should receive appropriate therapy. Results in the treatment of endocrine dysfunctions in this series of cases is irrelevant at this time except where such treatment caused a reduction of weight. The authors feel, as does Falta,⁵ Kenyon,² and others, that glandular therapy itself has little or no effect in reducing the weight of even the frank endocrine cases.

THIRD OBJECTIVE IN TREATMENT

The third objective is to prevent, after normal weight has been reached, a return of the surplus. Such a return happens to be a very common occurrence. It is necessary, therefore, to estimate the amount of energy the individual ordinarily expends, and from the figure to calculate the daily food need. It is absolutely necessary to teach the patient the importance of the food intake in the regulation of weight and

to educate him to the point where he can estimate his own food

CASE HISTORIES

The following three cases are selected from those that have been under complete control of the authors in the metabolic ward of the City Hospital in New York City for a considerable period of time. They are illustrative of the efficacy of the low calorie diet in any form of obesity.

CASE 1—Bella G., single 22 clerk, intelligent. Admitted to Metabolic Clinic, Midtown Hospital, July 15, 1930, referred from Medical Department as pituitary obesity. She had been under glandular treatment at another hospital for over a year.

Comment—This is a case of extreme obesity. Such subjects are generally classified from clinical standards as hypopituitarism. However, it was not possible to confirm this by any known tests for pituitary disease. Her year's treatment at the previous clinic is typical of the great majority of the ambulatory obese seen by the authors. Endocrine treatment, largely thyroid is often given in connection with a reduction diet. No weight reduction occurs from any glandular product except thyroid. When this is given in doses of around 15 gr a day there may or may not be a loss of weight but there are frequently seen, before the end of the second week, troublesome thyrotoxic symptoms. These toxic symptoms usually occur before there is any rise in the basal metabolism.

She claimed a normal intake. This would seem to point strongly to a glandular imbalance, but

Chart I—Showing the steady loss of weight while on weighed low calorie diets. It also brings out the fact that the weekly losses are not identical even though the food and fluid intake and the energy expenditure is the same.

and gained weight steadily during that time. She had a number of attacks of thyroid poisoning and for that reason sought other care. Weight on admission 283 lb., height 5 ft 1 in., physical and endocrine examination negative. She was positive that she ate less than most people she knew and had no craving for sweets. On a 1,600 calorie diet in the clinic she gained 2 lb. in two weeks. Though given instruction in food values the weight stayed at 285 for several weeks. She did not report for six weeks and then telephoned she was 297 lb. This situation brought about admission to the ward at City Hospital (10-21-'30). She claimed that at twelve the weight was normal. The tonsils had been taken out and following that she put on weight. At fourteen her weight was 188 lb.

The first week at the hospital was taken up with examinations, all of which were normal. On 800 calorie obesity diet with fluids restricted to 1,200 cc. and a salt poor diet she lost weight to 261 at time of discharge seven weeks later. No gland treatment was administered.

She was readmitted 9-23-'31 weight 298 lb. Put back on previous regimen. She lost to 235 lb. on 1-30-'32, i.e., 63 lb. in about four months. No acetone or diacetic acid at any time.

it was possible to prove the contrary. With weighed diets and good control her weight dropped at the same rate as those that admitted an excessive intake, in fact the full 3 lb. a week expected of anyone on her proper diet.

She gained weight while taking thyroid in connection with a so called restricted diet. This is a very common occurrence. To the authors it means that the diet was not observed and controlled. It would seem that if the thyroid corrected the endocrine dysfunction, which it is supposed to do in these cases there would be no need of giving any consideration to the diet. He felt that those cases under thyroid treatment who adhere to their diets lose weight while the others gain. Hence the diet plays the most important role in this treatment.

CASE 2—Bessie S. Admitted to City Hospital 9-30-'31. Discharged 12-22-'31. Admission diagnosis pituitary obesity.

Age 28. Married. One child. Height 61.25 in. Weight 313 lb.

Mother died of diabetes mellitus at 39. Menstrual history normal. Weight came on fast following appendectomy seven years ago. A mentally alert young woman with pituitary distribution of fat. Admits being a good eater.

B.M.R.: -6 and +9. 10-5-'31 fasting blood sugar 180 mg. 10-8-'31 sugar tolerance test 145-250-250-250-260-265-130. Put on 800 calorie diet, restricted fluids and low salt diet. Most of the days, however, she did not eat over 600 calories. Her weight drop is shown in Chart I.

On 11-30-'31 she showed acetone and diacetic acid. Had a sore throat and a temperature at that time. No urine showed sugar or was there any history of glycosuria.

Comment.—This woman gives a diabetic family history though she has never shown sugar in her urine. She has a definite diabetic tolerance curve. She lost the expected number of pounds for the total number of weeks, though some weeks she lost considerable while other weeks she showed no loss.

She is an example of the clinical observation, that obesity is often the forerunner of diabetes. It is interesting to note that even with her pre-diabetic condition the low calorie diet did not produce acidosis until an infection occurred.

CASE 3.—Mrs. B. H., 46, married. No issue. Admitted to City Hospital August 4, 1933. Height 5 ft. 5 in. Weight 363 lb. Most of family overweight. Father 6 ft. 4 in. Weighed 400 lb.

Up to one and a half years ago when her menopause occurred she weighed 250 lb. Gained thereafter almost 2 lb. a week. Treated at clinic for a short while with thyroid extract. Did not lose weight but developed severe thyrotoxic symptoms. Sought hospitalization thereupon.

Termed pituitary obesity by several medical consultants. Eye examination negative. X-ray showed calcification within sella turcica. Sugar tolerance curve 118-210-236-174. B.M.R. +15 and +12. Put on diet of carbohydrates 36.6 gm., proteins 61 gm., fat 10 gm., according to Strang and Evans. Fluids were restricted to 1,000 c.c. and a low salt diet given. The weight curve is shown in Chart I.

Comment.—Patient still on treatment January 30, 1934. Has no complaints. Never showed ketonuria and gives no signs of anemia. She likewise has a diabetic type of blood-sugar curve without a history of glycosuria.

SUMMARY

1. Weight reduction by low calorie diets is a very simple and positive procedure when there is complete control over reasonable periods.

2. Diets of 400 to 800 calories give on the average a loss of 3 lb. a week.

3. No difference was seen in the rate of loss in the cases clinically diagnosed as "endocrine."

4. Contrary to the well-entrenched common belief that most of the endocrine obese

eat no more or perhaps less than the average, it was found that the vast majority of the patients admitted a large intake. This was especially true in the cases of Fröhlich's syndrome.

5. There were a few, however, that vehemently and persistently claimed a low food intake. The authors had considerable opportunity to test this group and in every case, as in Case 1, it was found that these patients were in error and that they reduced at the same rate as the admittedly heavy eaters.

6. After the first week there were no complaints about the appetite, rather the patients asked for further reduction of food.

7. Most of the blood counts taken at the end of the treatment were well within normal. The *bête noir*, ketosis, was conspicuous by its absence.

8. Because so few instances of minus basal metabolism were found and because most of these patients had at some previous time used thyroid extract with bad results, practically no thyroid therapy was employed.

CONCLUSIONS

1. The authors are convinced that the low calorie diet as suggested by Strang and Evans is the most valuable method of reducing the weight in the obese that exists at present.

2. In both the endocrine and nonendocrine cases weight losses are in inverse ratio to the number of calories in the low diet.

3. Complete control is essential to success in reducing weight.

FEWER AND BETTER NURSES NEEDED

There are too many nurses in the State in relation to the demand for them, too many poor nurses, too many nurses inadequately prepared for their work in the community, and too lax control of their practice. Fewer students of better quality, with more adequate clinical and theoretical preparation, fewer schools and these under educational

auspices, and control of those practicing nursing are needed. That is the finding of an intensive study of nursing education and practice in this State made by the State Education Department during the past two years in an attempt to determine how adequately present curricula prepare nurses for their work after graduation.

WHEN SHOULD A SENILE CATARACT BE REMOVED?

ARTHUR J BEDELL MD, FACS

Albany

When a senile cataract should be removed is dependent upon many factors each of which must be considered in its relation to an individual patient. The simple rule of a few years ago, that the best time for operation was when the iris shadow had disappeared has, fortunately for the patient, been replaced by a rather complicated clinical and economical investigation, the results of which not only hasten his return to work but also minimize the operative risk.

It should be obvious that before a patient is subjected to this surgical procedure that his body health and ocular state should be thoroughly studied. It should in like manner be evident that before a diagnosis of operable cataract can be made, the examiner must be thoroughly familiar with the congenital and developmental changes which may be found in the lens.

Changes in the embryonal nucleus are usually circular and consist of very minute white spots placed near or in the center of the lens. They are easily seen with the slit-lamp but difficult to photograph. They remain stationary throughout life and do not influence vision.

The fetal nucleus corresponds in size to the lens at birth and on its anterior surface is an upright more or less clearly outlined Y and on its posterior an inverted X. A cataract involving this nucleus is usually greyish white, has a tendency to extend into the adjacent zone and may not be a complete ring or layer. On the periphery of this nucleus we frequently find opacities curving over the anterior and posterior surface of the outer rim. These hooks or riders vary in number, density, and visibility. Lamellar cataract seems to indicate that a state of malnutrition existed when the clouded lens fibers were formed. It is probable that the most common type of congenital cataract is zonular, the entire infantile nuclear layer is opaque. There is little difficulty in diagnosing this cataract by oblique illumination and ophthalmoscopic examination, but its minute construction can only be determined by means of the slitlamp.

The adult nucleus almost invariably shows some changes in surface contour like

knobs or depressions suggesting the segment formation of the lens. These rarely, if ever, reduce vision. The commonest cataract of the adult nucleus is in its lower nasal side and consists of irregular whitish gray opacities.

The thin but ever growing layer between the adult nucleus and the capsule is in the cortex. In discussions we should be very particular that when we refer to a cortical cataract, we mean only this portion of the lens. The first sign of a senile cataract is the widening of one or more spaces in the cortex. At first these are transparent water clefts. Soon, however, there is a distinct formation of globules in these fissures, followed by visible thickening of the outlining edges. The process may be rapid or slow, steadily progressing or intermittent or it may advance to a certain stage and then remain unaltered for years. Incidentally, it should never be forgotten that drugs have no influence on its growth and cannot either hasten or delay maturity.

Globules or vacuoles may appear in any part of the lens but they are most often found in the cortical layers. They may be single, round, oval, or kidney-shaped. They vary considerably in size from minute bubbles to large, lake like spaces. In fact, in one type of senile cataract almost the entire cortical layer in apposition to the capsule seems to be liquefied, suggesting in appearance a film of oil globules.

If we comprehend and follow the anatomical subdivisions, it will be possible to distinguish two definite, distinct types of senile cataract, the differentiation depending upon the amount of fluid imbibed and retained by the lens fibers and the spaces between them. In one there is liquefaction of all but the central portion of the lens which seems to correspond in size and shape to the fetal nucleus.

As the lens fibers swell and break down, the brown nucleus floats in the fluid. At or before the time of this nearly complete liquefaction the capsule becomes thickened, denser, and more resistant to operative manipulation.

The other type of senile cataract is characterized by the absorption of fluid which may be continuous or interrupted. The

lens becomes more and more opaque and definitely thinner so that if operation is long delayed, almost all of the lens fibers may be absorbed leaving an irregular folded lenticulocapsular membrane. We have observed the stages through which this type cataract passes and find that round and oval white spots may develop in the anterior cortical layer. These deposits may increase in size, show definite yellowish calcification or even the iridescent crystals of cholesterol.

A patient who has any form of congenital cataract, may later have a typical so-called senile cataract. It is important that, if possible, we distinguish between the congenital lens changes and those which have come after the adult nucleus has been formed. The reason for this is that we have anterior subcapsular opacities as well as the more common posterior ones. Either may indicate an intra-ocular disease. For instance, in retinitis pigmentosa we may have a single globule in either the anterior or posterior cortical layer, but frequently as the disease progresses a rosette-shaped mass is formed. This must not be mistaken for the early signs of posterior cortical cataract which consists of a sheet of radiating opacities giving the impression of irregularly rounded, clear spots, which look like a sieve of various-sized meshes. These should not be confused with a traumatic cataract which is characterized by feathery extensions from the lens segment lines.

It is not the intent of this paper to discuss the condition of the conjunctiva or lacrimal apparatus.

After this preliminary review and summary of lens opacities, we should consider the individual eye. Is there iris atrophy? Does the pupil fail to dilate because of that or as the result of posterior synechiae? Is the anterior chamber of normal depth? What is the actual state of the lens capsule, is it tense or relaxed? Then we consider the patient's general health. Has he active foci of infection? If so, is the iris edematous? Has he diabetes? Has he syphilis? Has he retinitis pigmentosa? Has he hypertension or has he macular degeneration?

If he has hypertension, when should he be operated on, after a long period of rest, after the administration of tension reducers, or following a few hours of relaxation in the hospital in which the operation is to be done? This is debatable. Personally, I believe that the patient does best when his

cataract is removed shortly after his hospital entrance and without attempting to reduce his hyperpiesia.

When the patient has diabetes, should he have insulin? Should he be starved? Should his blood sugar be brought to the minimum or should he be operated upon as soon as there is a definitely established sugar tolerance? After reviewing our cases of cataract in the diabetic, we are inclined to believe that overinsulation has produced less satisfactory results.

It is probable that most of the readers will agree that when a patient has nonactive but Wassermann-positive syphilis, we should operate without waiting for a negative blood reaction.

In the presence of glaucoma, we should be exceedingly careful to exclude active uveitis before attempting cataract extraction. If the field of vision is extremely contracted and if the tension has persisted for a long time or if tension-reducing operations have failed, the removal of the cataract is attended with extra risk and with much less chance of a favorable result.

From the economic standpoint, the time to remove a senile cataract should to a great extent, other things being equal, be influenced by the ability of the patient to continue at his usual occupation. If the vision of one eye with or without correction is normal, or approximately so, it does not seem to me that we are justified in extracting the cataract. This opinion is given after many years of close observation of patients who have presented with one cataract. It is not an absolute rule, however, for some desire to have the lens taken out for cosmetic reasons. When a young person has a cataract it is often advisable to remove the lens before secondary disintegration takes place.

If the patient has bilateral, progressive, incomplete senile cataracts, and is unable to do his ordinary work, one of them should be extracted by the intracapsular method. I think all conservative surgeons agree that even if the patient has bilateral cataracts it is much safer to operate on only one eye rather than both at the same time.

If there is little ocular interference with work and if one cataract is much farther advanced than the other, the ideal time for operation as determined by slitlamp examination, seems to be when there is complete opacification and a thin but demonstrable collection of globules beneath the capsule; when the lens has returned to its normal

thickness, when the anterior chamber is of normal depth, and when the field of vision indicates sufficient function to warrant intervention. In the desiccated or dehydrated lens the preferable time is when the opacity is complete. Under these conditions the safest procedure can be performed with the least risk to the patient. It is in the determination of these optimal periods that the slitlamp examination proves its value.

To summarize, experience and diagnostic skill are necessary to determine the type and degree of maturity of any senile cataract.

When both eyes are involved and the patient is unable to work, other things being favorable, the intracapsular method is to be preferred. When one eye is affected and the other has good function, the ideal time for operation is when the lens is completely opaque and the anterior chamber of normal depth. When the cataract is caused by, or incident to, constitutional disease, careful consideration must be given to such complicating factors and, finally, the diagnosis of senile cataract is made most accurately after slitlamp examination.

WHAT PROGRESS HAS BEEN MADE IN PERFECTING THE CATARACT OPERATION?

BEN WITT KEY, M. D.
New York City

It is fitting and always of value in the development of surgical methods, to stop and look about us at times and to take stock, as it were, of the ever changing techniques and methods in the perfection of operative procedures. In recent years, these changes have been so marked and of such inestimable value in perfecting the operation for cataract, that the writer is led to present what progress has been made.

ASEPSIS

From the viewpoint of asepsis, the preoperative measures as well as those at the time of operation must be recognized. Of the many methods employed, the writer believes a solution of argyrol, or mercuriochrome or zinc sulphate, three times a day for three or four days prior to operation has been the usual procedure. Silver nitrate, 1 per cent, one or two hours before operation, has been strongly advocated and no doubt has its value. Of these methods the writer's preference is that of zinc sulphate solution, $\frac{1}{2}$ per cent, three times a day for three or four days prior to operation. Irrigation of the lacrimal sac with zinc solution on the day before operation is always good practice. A laboratory report of a smear from the conjunctival cul de sac on the day of operation has long been regarded as a valuable indication of the bacterial content.

At the time of operation, it is now believed to be advisable to paint the brow and forehead and lids with tincture of iodine.

3 per cent, and neutralize with alcohol, 60 per cent. The cilia and lid margins are also treated in the same manner and the cilia of the upper lid are excised. This toilet of the parts requires a little time, if properly carried out, but without any doubt whatever, it is an essential part of good practice to day. As to the other commonly employed methods of irrigation, etc., suffice it to say that since the autoclave has entered our operating rooms—and these local measures have been carried out—the percentage of infections has diminished to the point that now one is very rarely encountered. The author has seen 2 cases in twenty four years of practice and these were observed about nineteen years ago.

PHYSICAL CONDITION OF PATIENT

Even before the discovery of local anesthesia it was recognized that the physical condition of the patient was an important factor which determined the success of the operation for cataract. Pathologic studies, both systemic and ocular, have taught us the causal relation thereto, and especially those related to arteriosclerosis, toxic conditions, foci of infection, etc. These things, being true, it has come to be the part of good practice to eliminate, or at least to understand in some detail, the systemic condition of the patient prior to operation. It is hardly necessary to emphasize the importance of diabetes, hypertension, nephritis, decayed teeth, tonsillar infection, etc., as being often responsible for complications.

which could have been avoided by corrective measures previous to operation. It appears to be accepted universally that the cataract operation has been perfected in recent years by the more rigid investigation of the patient's physical condition.

ANESTHESIA

The introduction of butyn as a local anesthetic which does not dilate the pupil, and the advent of subconjunctival injection of 2 per cent cocaine solution have been recognized as definitely progressive measures in perfecting the cataract operation. Dilatation of the pupil in cases where the anterior chamber is normal or shallow, diminishes the depth of the iris angle and therefore mechanically prevents in many cases the correct introduction of the knife, and especially at the counter-puncture. The use of butyn, instead of cocaine or holocaine, will permit the next stage of anesthesia, subconjunctival injection of cocaine, 2 per cent, without pain, and thus complete anesthesia is secured in the course of four or five minutes. The section is made as the pupillary response to cocaine injection is noted. This simple method of producing complete anesthesia without mydriasis and without exciting the patient nervously at this critical time is undoubtedly a progressive step in perfecting the cataract operation.

Retrobulbar injection of novocaine or procaine has been advocated by many excellent authorities, and although undoubtedly most satisfactory in their hands, it seems entirely unnecessary compared to the simple method of subconjunctival injection.

In very unusual cases, where general anesthesia has been indicated, the use of avertin has been widely heralded during the past few years as being a progressive method. This no doubt is true, but it must be administered by an expert, and it must be understood that it greatly reduces the ocular tension at the time of operation. Its field is undoubtedly a positive one and, when more experience is gained by its use in ophthalmology, it may displace ether and chloroform, which are now very rarely indicated. Because of the effect of avertin in markedly reducing the intra-ocular tension, cases of cataract with hypertension are regarded as the most suitable for the use of it. To employ avertin because of the nervous state of the patient seems unnecessary, because in these cases an injection of hyoscine, morphine, and cactine—tabellae

No. 1 or No. 2, (No. 1 containing $\frac{1}{4}$ gr. of morphine, or No. 2 containing $\frac{1}{8}$ gr. of morphine) made by the Abbott Laboratories—fifteen minutes before the patient is brought to the operating room, relieves the nervous element which may be present and rarely produces any postoperative nausea. Luminal, $1\frac{1}{2}$ gr., previous to operation is also a very valuable measure for the same purpose and has been employed by the most conservative ophthalmic surgeons.

CONTROL

The factor of control of the patient has for many years been entirely a personal one. It has implied in many instances training of the patient by the surgeon previous to operation. This was often due to lack of confidence on the part of the patient, or more commonly a form of sheer ignorance or perhaps fear of pain or of an unsuccessful result.

But now, that is, in the past few years, while we still desire the confidence of the patient and must insist upon some personal control, the local control of the lids has been solved by the simple method of novocaine injection, blocking the orbicular branches of the facial nerve. Three per cent novocaine solution injected along the temporal rim of the orbit, and 1 c.c. of the same solution at the nasal portion of the upper lid, and also at the nasal portion of the lower lid renders the patient incapable of forcefully squeezing the lids. Although a very simple method, it is known to be absolutely trustworthy, if the novocaine is so, and if correctly injected. Blocking of the facial branches of the nerve by preauricular injection of novocaine is another method of performing the same service, and is employed by many of our best surgeons, but again the simplicity of the former method commends itself more favorably to the profession.

Retrobulbar injection of procaine hydrochloride combined with epinephrine, after Elschnig's technic, for the purpose of anesthesia, also tends to immobilize the globe—a type of akinesia which is believed to be a great advantage, and especially because the intraocular pressure is reduced by this injection. Thread fixation, after Angelucci's method of application, is another measure advocated for local control of the globe, and is enthusiastically recommended by de Grosz who uses it in every case.

Fixation of the globe with suitable fixation forceps, which have a deep biting grasp, seems to be exceptionally satisfactory for this purpose, when the lower third of the internal rectus is grasped. This fixation not only controls the downward rotation of the globe, but "steadies" it and offers most effective resistance to penetration of the knife both at the puncture and at the counterpuncture, which aids in permitting a smoothly made section by two sweeps of the blade.

When one recalls the hazards of cataract extraction twenty years ago in cases almost spastic with fear, timid and ignorant, and frequently of alien blood, unable to be understood or to understand directions—all this and without the methods of anesthesia and control of the lids and globe now employed—one must realize the magnificent developments which have taken place in the past few years in perfecting the operation of cataract extraction.

CONJUNCTIVAL FLAP AND SUTURES

The technic of operation by making a square-shaped conjunctival flap, when the corneal section is made, and at once placing two French silk (No. 000) sutures at advantageous points in the flap is undoubtedly one of the most valuable steps in the progress of perfecting the cataract operation. This, the author believes, must be universally accepted in the course of time. Many authorities regard it as unnecessary, cumbersome, and an added manipulation and irritation attending the operation. On the contrary, it is the writer's conviction, that it is not irritating or cumbersome when properly carried out, and furthermore, it has many exceptional advantages. The conjunctival flap is an aseptic measure, and aids in the nourishment of the corneal section; it is a protective measure during and after operation, and undoubtedly affects the degree of postoperative astigmatism.

The sutures, when placed each just above the pillars of the coloboma, and carried at an angle (not more than 15 to 20 degrees) on either side through the bulbar conjunctiva, produce a bit of traction on the flap upward and laterally, so that the lips of the corneal wound are sealed tightly in place when the sutures are tied. This is recognized and its value appreciated, when the spatula is used to replace the pillars of the coloboma. These two sutures are not cumbersome or obstructive in the precision of

technic. They are so placed after being inserted, that they are not in the line or direction of the cataract, when being extracted. After extraction of the lens is completed, each is tied almost to the conjunctival flap as a means of protection, and when the operation is finished they are tightly tied. Their presence after operation is unknown to the patient, no noticeable irritation is observed, and by the seventh day they are usually found on the dressing or free in the cul-de-sac. The removal of them, when necessary, is of no consequence. It must be understood, however, that the character of the silk suture must be French silk No. 000, and no substitute for this yet employed by the writer is comparable.

The safe-guard that is felt after operation, when a suitable conjunctival flap is firmly sutured in position, is well worth the time and precision of making it a part of the essential technic of the operation. The conjunctival flap and sutures are not advocated because of anticipation of vitreous loss, although they are protective measures in this respect, but more especially is it essential because of the fact that undoubtedly it permits a more perfect replacement of the iris pillars and restoration of the anterior chamber in twenty-four hours. Since using this technic, the writer has not seen a case of hypertension after cataract extraction. The advantages of this technic are at once suggested by the mere description of it, but they multiply in number when one has employed it over a brief period of time.

It is well known that the character of the section made in cataract extraction is one of the most important steps in the technic, especially as to the size, location, and smoothness of the incision. The precision of this procedure is somewhat dependent upon the judgment of the operator as to the pathology of the cataract to be removed, which will, of course, determine the size of the section in the particular case. The conjunctival flap and sutures do not obstruct extraction of the cataract, as often occurs in extraction by the method of making a conjunctival bridge. In these cases the corneal flap is not held tightly in position, as occurs when suitable sutures are placed.

CHOICE OF OPERATION

The progress made in recent years as to the pathology of the cataractous eye—especially as to the character of the lens,

its size, consistency, the capsule, and its zonular relationship, etc.—has made it clear how, in varying degrees, these may differ. For this reason, the judgment of the operator is challenged as to the choice of the operative procedure to be employed in the particular case. The question arises as to the choice of a corneal section or a conjunctival flap, the choice of a combined extraction or after preliminary iridectomy or a simple extraction, the choice of extracapsular or intracapsular extraction. It seems to be conservatively accepted that one method of extraction is not suitable for all cases, and especially when the purpose of the operator is to give this patient before him the safest procedure that will yield normal vision and a healthy eyeball. It is agreed that a number of different methods skillfully carried out in the same case may yield normal vision, but the hazards of one method over that suitable for the particular case must be recognized and the welfare of the patient seriously considered.

Here, perhaps, in the choice of operation for a given case, lies the most delicate question before us, because one's prejudice should not overrule the actual pathology and mechanical status of the case. For example, to attempt to make a large section and tumble the lens in intracapsular extraction in a case with very shallow anterior chamber and a swollen fairly soft lens, does not seem to ring true to the conservative judgment required. In such a case it is the writer's view, that a narrow cataract blade should be used, that the section should be smaller than is usually required, that the anterior capsule may be removed with Schweiger capsule forceps or a suitable cystitome incision made, and the lens removed in the usual manner of twenty-five years ago.

On the other hand, in certain types of so-called "green cataract," with nuclear sclerosis, or in hypermature cataract, or in the "pepper and salt" type, or in those found in retinitis pigmentosa, in which cases the anterior chamber is deep and the capsular attachment permits, a large section may be made and the lens removed by combined extracapsular extraction or by the intracapsular method as the case may require.

The factors which should govern one's judgment in the choice of operation for the given case are: (1) the age of the patient; (2) the character of the cataract—imma-

ture, hypermature, nuclear sclerosis, complete sclerosis, complicated cataract, "pepper and salt" type, etc.; (3) the character of the capsule—tightly drawn, fibrous, or green capsule; (4) the depth of the anterior chamber; and (5) the temperament of the patient. It is unnecessary here to discuss these factors in any detail before this enlightened Society of ophthalmologists, but it is fitting to call attention to the fact that the choice of operation, dependent upon these factors, has been a most progressive step in perfecting the modern extraction of the cataract, and is undoubtedly one of the reasons for the large percentage of perfect results enjoyed by the public and by the profession at this time.

INSTRUMENTS

Modern instruments of precision for the cataract extraction are certainly recognized as a progressive step in perfecting the technic of the procedure. Of these the writer believes the speculum of Webster Fox, and that of William Lister, and the lid retractors of Lang and Fisher deserve special mention. The fixation forceps with a long, deep grasp (patterned after Lang's) for the purpose of engaging the lower border of the internal rectus is an instrument devised recently which fixes the globe so rigidly that the section can be controlled with great delicacy.

Two types of cataract knife are now made by Weiss, London, one $1\frac{1}{2}$ mm., the other $2\frac{1}{2}$ mm. broad, with a straight cutting edge, directly lance-like to the point, and without any change in the width to form a belly along the cutting edge. The narrow blade is used where the anterior chamber is shallow, the broad blade is used where the anterior chamber is normally deep. The mechanics of the procedure in making the section explains at once the value of these knives, since the iris is little exposed to trauma, and the counterpuncture can be made with precision. A cataract knife with a curved cutting edge, or belly, is obviously unsuitable for making a cataract section.

The capsule forceps of Schweiger for removing the anterior capsule of the lens, and those of Elschsig for removal of the lens in capsule are delicate expressions of the art of instrument-making, which deserves deep appreciation of their great value in perfecting the technic of this operation.

Many other instruments might be mentioned here, which aid in certain cases to perfect the technic, such as the delicate malleable repositor, the small spoon, the expression hook of A. Wilson, the mouth suction apparatus (Teale), the automatic electric suction machine (erisphake of Barraquer), etc. Suffice it to say that our instruments of to day have greatly improved the technic and lessened the hazards formerly experienced in the extraction of cataract.

POSTOPERATIVE CARE

After an experience of twenty-four years the writer is convinced that the postoperative care of cataract cases is almost universally underestimated as to its value in avoiding immediate complications and in the preservation of the normal cataractous eye. This so called aftercare, begins at the time of operation, because every cataract extraction should be performed in the bed in which the patient remains after operation. That the most critical time after operation is that immediately following it for forty eight hours, is certainly appreciated by all authorities on this subject. There can be, therefore, no excuse for moving a patient from an operating table to a rolling stretcher, thence to the elevator, from the elevator to his bedroom and again lifting him from the stretcher into his bed. The mere description of the procedure speaks for itself, and especially so when we know that in an extraction made with conjunctival flap and suitably placed sutures, the anterior chamber begins to reform by the time the bandage and mask are properly placed.

The value of competent nursing service for the first forty eight hours, day and night, has come to be a recognized postoperative necessity. Of course, this service for at least four or five days is especially desirable and should be secured whenever possible to do so.

The postoperative treatment of these cases is well known and is generally agreed upon. But in particular may be mentioned the use of an atropine solution of 3 per cent, which the writer believes is unnecessary and often precludes secondary glau-

coma. Atropine solution of 1 per cent is of sufficient strength to avoid iritis and does not produce excessive dilatation of the peripheral iris fibers.

Many minor details employed in the postoperative care of these cases might be mentioned here, but with little advantage to those who have their own methods of avoiding the dangers which may threaten the patient so personally helpless following this operation. Suffice it to say that the ounces of prevention, which have been learned in the care of these cases, have been definite measures of progress in perfecting the cataract extraction.

CONCLUSIONS

Given a healthy uncomplicated cataractous eye, it is believed reasonable to assume at this time that with the progress, herein outlined, which has been made in recent years in perfecting the cataract operation, the patient and the oculist have every reason to anticipate the most satisfactory result—a healthy aphakic globe with normal vision.

The special measures herein outlined may be enumerated as follows:

- 1 Aseptic measure before and during operation
- 2 The physical wellbeing of the patient
- 3 Anesthesia locally complete and simply applied: butyn and subconjunctival cocaine solution
- 4 Control of the patient, and local akinesia of the lids and globe
- 5 Section with conjunctival flap. Two sutures advantageously placed
- 6 Choice of operative procedure in each case
- 7 Modern instruments of precision
- 8 Postoperative care is emphasized

It may seem somewhat presumptuous here to use the term "perfecting the cataract operation," but this is chosen as an ideal toward which we strive, and, as the writer has pointed out, includes the knowledge of the pathology present and the judgment of the surgeon who performs the operation. May the progress in perfecting this operation continue with the years.

100 WEST 59TH STREET

DISCUSSIONS OF DR. REDELL'S AND DR. KEY'S PAPERS

DR. ALBERT C. SNELL. In my opinion the answer to the question: When should a senile cataract be removed?, may be based almost entirely on three fundamental considerations

provided, of course, that the cataract is an operable one, which generally means that there is evidence of no serious inoperable impairment of vision, no active source of infection in conjunc-

tiva or lachrymal duct, and no active or acute inflammation in the eye, especially in its anterior segment. The three essentials to be considered are: First, the condition of general health of the patient; second, his economic status; third, his social status. In considering general health we must decide whether there is a contra-indication to operation because of the age of the patient, the degree of senility or feebleness, and a probable short life expectancy. We would all admit that there is no suitable time to operate on an aged person in feeble health when even the confinement in the hospital and in bed for a few days would greatly jeopardize such a patient's life; neither would we operate when the span of life is reasonably sure to be of short duration. When no such serious obstacle is presented, the time selected for operation also depends on the probable effect the condition of general health may have on the outcome of the operation itself. I have reference especially to the influence of focal infection, kidney lesions, diabetes, and hypertension. In my judgment these conditions so far as they can be improved within a reasonable period of treatment should be corrected before undertaking a cataract extraction. Yet none of them are absolutely a contra-indication to the operation, even if they do not yield to treatment.

The second, the economic status, has a very important bearing on the proper time to operate. If a patient is dependent on his eyesight for a livelihood and for the support of his family, an early operation is indicated and should be undertaken before vision is reduced to such a point that the patient may lose his job or be unable to earn a living. The kind of cataract or the condition of its maturity is no deterrent in considering this factor under modern technique of intracapsular extraction.

The third consideration, the social status, takes note of the individual's position in life, his desires and social obligations. It relates largely to the individual's happiness and contentment or otherwise, with his condition of imperfect vision. For example, some patients have retired, and even if they are not able to read ordinary print with any aid, are very happy and contented with their lot. Such patients at times have a great dread of the operation and under such circumstances I would not urge an immediate operation. However, such patients, especially those with the probability of many years ahead, may be informed that with advancing years the operation may present greater difficulties because of hypermaturity or because of later feebleness or of ill health.

Dr. Key has described in detail the perfecting of the cataract operation during recent years. By employing these refinements the hazards of cataract operation have been greatly decreased and the intracapsular operation has become relatively the safer operation. Still, the choice of operative technic depends to a very large degree upon the skill which the individual operator has developed, using his individual technic. A successful method should not be changed hastily. Personally, I much prefer the intracapsular operation in all possible cases. We feel very sure that this operation is not more hazardous than the operation done with capsulotomy, provided that the operator has acquired some skill with the technic. Under modern technic the cases in which vitreous is presented or lost are even less than under the old form of operation and post

operative complications are rarely seen with the successful intracapsular operation. Any operator can become skillful with this method if he will carry out most carefully the technic as described. At first select the more favorable cases and be sure to have a good assistant. The intracapsular operation is the operation par excellence.

DR. ERNEST F. KRUG: More than ever an exhaustive examination prior to operation and a thorough understanding of all the factors which have led up to the formation of the cataract and the exact state of the eye, its spacial relations, the type of cataract, etc., is necessary for the proper selection of the cases suitable for operation. I wish to draw particular attention to a careful study of the state of the pupil and its reaction if disturbed, to determine whether the abnormality is due to a diseased eyeball or to the mechanical interference of a swollen lens. Importance is placed on the facts of not only determining the projection but also the acuity of central vision to forestall the disappointment of a poor result after a good operation, due to senile macular changes, with central scotoma. I shall confine my remarks to such complications as arise as a result of the surgical interference itself.

As for the preparation for operation: There is no excuse to my mind, for an infection at the time of operation. A negative smear should not require much treatment of the conjunctival sac. The routine cleansing of the lachrymal sac is a good procedure. Twenty per cent argyrol instilled several times prior to operation and irrigation of the sac should be sufficient. The patient should not be in the hospital too long before the operation. We try to have the patient in the hospital for forty-eight hours for the necessary examinations and laboratory reports.

As for medication: Luminal in dosage according to the nervous condition of the patient and never morphine or its derivatives, has proven satisfactory and no medication per mouth after the operation. For the usual complaint of backache and restlessness, a suppository of $\frac{1}{2}$ gr. codeine, 10 grs. of aspirin, which can be repeated every four hours, has been most satisfactory.

We must all admit that a surgical procedure with the least possible trauma to the eye—and that means the minimum of instrumentation and steps in the operation—must give the best result. The operation should be simplified, not complicated, by unnecessary steps. The ideal operation would be, a section, a dislocation of the lens from its suspensory ligament, and its delivery from the eye with the least possible pressure upon the globe.

No one will dispute the superiority of a safe intracapsular extraction followed by none of the dangers of retained lens substance and capsule, and the formation of the troublesome secondary cataract.

The Kalt forceps, although it is not perfection, we have found to be the safest and most dependable of all the forceps at our disposal.

Dr. Key has told us of the new methods of anesthesia; a real step forward toward minimizing the risks of the operation. One should be exceedingly careful not to strike a blood vessel in the injection. If this happens, it can be most annoying.

After 25 years of cataract surgery, I am still convinced that the traumatism at the time of operation is the cause of all complications with

few exceptions. We can no longer place the blame of a poor operation upon the behavior of the patient. This applies now as an exception rather than a rule.

To me, the section still remains the most important step of the operation. I am careful to note that the spring of the speculum used is weak, and its insertion should be accomplished without touching the skin of the lids. This means that it should be closed when placed under the lids, then opened slowly to the necessary width when it has been inserted below the lids and only when the control of the orbicularis is assured. The fixation of the eyeball must be firm. The fixation of the tendon and the internal rectus just below the horizontal meridian has given me the firmest hold. The use of a fixation forceps without a catch has been advised because one is able to let go the hold upon the eye at once in case of accident. For me, the fixation forceps with a catch has assured the fixation and has cured me of the habit of exerting pressure upon the globe by too firm a grasp as was true before I used a forceps with a catch. One can remove such a forceps quite as quickly when it is in good working order in case of need.

The incision should be a deliberate and steady sweep of the knife without haste. Only then will the section be clean cut and it should never be less than $\frac{3}{4}$ of the corneal circumference. For the extraction in the capsule, it is necessary to enlarge this section to 180 degrees to allow the lens to escape. The section should never encroach upon the sclera. A conjunctival flap is desirable and can be attained with the section in the limbus. I do not believe in too large a flap. It can become very troublesome from bleeding and it can be disturbing to the nutrition of the cornea in the healing. Through the entire procedure there should be no pressure upon the eyeball and we know that it is not only the pressure of the lids but the pressure of the recti muscles, especially the traction of the superior rectus, which in a restless patient may bring about an early escape of aqueous and result in obliteration of the chamber with the danger of the presentation of the iris before the knife, and to avoid this, an injection of novocaine over the superior rectus is advised as a routine procedure.

As soon as the section is complete, the fixation forceps should be released and the speculum removed. With a proper skinness, it is not necessary ever to touch the lower lid and if there is a drooping of the upper lid this can be easily controlled with a lid hook.

The question of iridectomy. I can see no objection to an iridectomy. It opens the pupil, which is never as large as the lens and minimizes the force necessary to expel the lens. It opens the pupil only if the iridectomy is complete. We perform preliminary iridectomy on all patients with a shallow anterior chamber. It is always followed by a deepening of the chamber, assuring a better section at the time of extraction, and this brings me to the importance of knowing the tension of the eye.

One of the most unpleasant complications of the cataract extraction is glaucoma. If we carefully study the tension of our cases prior to operation we will find that not a small number of them are on the borderline of tension and in just these cases is a preliminary iridectomy indicated. In a cataractous eye, there is a change in the intraocu-

lar fluids and especially during the stage of swelling of the lens, a preliminary iridectomy can do no harm and usually brings about more normal spacial relations in the eye. We all try to remove the lens in the capsule. I for one cannot state in advance whether or not I shall be able to accomplish this in any one case.

When we are dealing with a cataractous lens we have either a soft or a hard cataract. By soft cataract we mean a lens with a comparatively small nucleus and more degenerating cortex which is either soft and fluffy or sticky, or actually fluid, as in the hypermature morgagnian cataract. The capsule of the lens is usually thin and easily torn. In the hard cataract we have a large, hard, sclerosed nucleus with very little cortex, a tough capsule, sometimes difficult to grasp and even to cut with a cystotome. The older the patient the weaker the attachment of the zonule to the capsule and the less difficulty we encounter in our attempt to dislocate the lens, but the attachment of the suspensory ligament to the capsule is relatively weaker in the soft cataract than in the hard.

We are indebted to Dr. Arnold Knapp for having shown us a safe and conservative method of removing the lens from the eye in its capsule and if the attempt is made, the lens is grasped below with a Kalt forceps and gently rocked from side to side with gentle traction. If it is a lens that will dislocate, it will do so almost at once. The procedure practiced by some operators to hold fast to the lens and withdraw it with the forceps from the eye, is not without danger of loss of vitreous. The tumbling of the lens as taught us by Dr. Knapp can be done without fear of accident and if one does not succeed in dislocating the lens the capsule forceps will tear off a large piece of the anterior capsule and the extraction can be completed in the usual way.

If the lens dislocates, the tumbling of the lens and its extraction from the eye should be accomplished with as little compression of the vitreous, choroid, and retina as possible. If the lens does not tumble, it will deliver in the upright position the upper edge foremost, presenting in the wound upon slight pressure below.

One of the most unpleasant complications in this operation is the loss of vitreous, immediately after the section, before the lens has been removed. I know that most operators proceed and remove the lens with a loupe. I have done this but it has always been accompanied by more loss of vitreous and an unsatisfactory result. It is a subject which I think we should discuss. Shall we deliver the lens with the loupe, or shall we stop and remove the lens at a later time? Gifford is strongly in favor of this.

We use a few drops of 1 per cent atropine before the operation and none after unless there is definite iritis. I prefer hyoscine if there is any evidence of iris irritation and I find it quite satisfactory especially in those eyes that, prior to operation are at the borderline of tension.

We should try to perfect ourselves in the extraction of the lens in the capsule. It gives us a clear pupil, no debris of soft lens and capsule to cause secondary glaucoma and the development of a secondary membrane necessitating a decision with its disturbance to the vitreous. I consider the decision operation fraught with greater danger than the extraction itself. With this clear

pupil we have the best visual results and if the operation is carried out deftly, there is less inflammation with less danger of inflammatory reaction, and a shorter period of convalescence and a more satisfied patient.

I want to emphasize Dr. Bedell's remarks against the promise of cures of cataract without operation. There is no way of stopping a cataract from maturing and those types of cataract which do not mature are not influenced by any medication and will not mature if they are left alone.

We no longer wait for the cataract to become mature in cases where the nuclear clouding so reduces the patient's vision that he can no longer carry on his occupation. With a nuclear type of cataract this comes on rather quickly. One should remove the cataract as soon as the ability to read is interfered with, and that means inability to carry on almost all usual activities. A patient's occupation also determines whether a unilateral cataract should be removed. A chauffeur, for instance, would be greatly benefited even if he could not wear a cataract glass, in that he could at least discern objects with the operated eye.

Let us not forget that a senile cataract is found in a senile eye, and the entire eye has undergone a change and even with a perfect operation, perfection cannot be expected in every case.

DR. JAMES W. SMITH: The lesson to be drawn from these excellent papers is that every cataract patient should have a careful preoperative examination, not only of the eye but the mind and body as well. I would like to ask Dr. Bedell

what his preoperative attitude is in cases of fixed diabetes with high blood sugar. Some authors attach very little importance to the presence of diabetes and I believe Dr. Vail of Cincinnati in a recent paper stated that the postoperative course was uncomplicated in a series of diabetic cataracts. Dr. Key stated that he gave his patients $1\frac{1}{2}$ gr. of luminal before operation. I have not found this satisfactory and have seen patients act as frisky as school children who have had as high as 3 gr. of luminal and even morphine preceding operation. I prefer to start the administration of phenobarbital about 8 hours before operation. I believe Dr. Snell's suggestion of beginning the administration of this drug the night before to be even better. Under the heading of anesthesia, Dr. Key mentioned O'Brien's modification of the Van Lint nerve block of the seventh cranial nerve fibers supplying the orbicularis oculi. I have in mind a patient who following this procedure presented the lip of the corneal wound between the lids at the first dressing postoperatively. Some operators dress their operative cases after 24 hours. I have always been at a loss to understand this procedure and why some surgeons to satisfy their curiosity are willing to replace a sterile dressing applied in an operating room under the most aseptic precautions for one in the ward of questionable sterility. It would be interesting if someone would present a paper emphasizing when a cataract should not be operated on and also stressing the accidents that have been known to follow cataract surgery.

NEW YORK CITY TO TRY GROUP HOSPITALIZATION

The State Department of Social Welfare has approved an application for the establishment of a nonprofit corporation to organize and administer a group hospitalization plan among the voluntary hospitals of New York and its suburbs. The establishment of the corporation, to be known as Associated Hospital Service of New York, now depends on the obtaining of funds to put the plan into operation and maintain it for six months; the payments of beneficiaries will provide the hospital benefits after that time. Governor Lehman recently approved a bill amending the state insurance law to permit development of this plan, which is sponsored by the United Hospital Fund, comprising forty-six voluntary hospitals. It is anticipated that about 100 hospitals participate, according to the *Journal of the A. M. A.* The proposed association would be controlled by eleven directors elected annually by a voting membership comprising the presidents of the Hospital Conference of the City of New York, the Brook-

lyn Hospital Council, the five county medical societies of New York, and the trustees of the United Hospital Fund. The individual cost would be \$10 a year and the service would be available only to the insured person, not to his dependents, though dependents may be included later, it is said. The subscriber would be entitled to three weeks of semiprivate hospital care after a ten-day waiting period immediately following the signing of the contract (this waiting period would not apply in cases of accident) and ten months in obstetrical cases. The subscription does not include fees for medical service. Admission to the hospital would be granted only on the recommendation of the subscriber's physician. The new legislation and the development of the group payment plan are the result of a study made by a special committee of the United Hospital Fund, of which Doctor Sigismund S. Goldwater, now city commissioner of hospitals, was chairman.

HOW TO SIZE UP STATE MEDICINE

We can judge what state medicine would be like in this country by looking at the sad conditions often prevailing under our compensation laws. Dr. Nathan B. Van Etten states in an informing article on health insurance in the *Literary Digest* that in forty-four states, compulsory compensation insurance laws involve similar expensive administrative machinery, which rarely is satisfactory and largely riddled with scandalous racketeering.

In small towns the schemes are sometimes meritoriously operated, but in every city in the country they are dominated by malignant influences.

Compulsory health insurance to replace contract practice might be a step forward, he observes, but in the United States, where most of the physicians are "on their own," compulsory health insurance would be a backward step from independent service, however poorly paid, to dead levels of governmental servitude.

THE PROBLEM OF THE PREMATURE INFANT

RALPH M TYSON, M D

Professor of Pediatrics Temple University Philadelphia, Pa

INTRODUCTION—The problem of the premature infant has been receiving attention by various groups of medical men for many years, but very little has been accomplished in reducing the mortality in this group of patients until very recently. Reports from various State agencies show that prematurity is the cause of death in approximately 25 per cent of all infants who die under one year of age. In Table I are given the infant deaths occurring during 1931 and 1932 in Pennsylvania, according to the records of the Bureau of Vital Statistics. This shows that prematurity was the cause of 24.3 per cent of the deaths in 1931 and 26.6 per cent in 1932. According to their records, there has been no decrease in this premature death rate in the past 28 years.

heat regulation and humidity control. Also, we must not lose sight of the fact that particular attention was given to the handling of premature infants and no doubt the doctors as well as the nursing staff were becoming more adept in these cases.

THE SOURCE OF MATERIAL—Material for the following statistics was secured from the records of the Philadelphia Lying-In Hospital covering a period of 27 months (Table II). During this period there were 4663 deliveries with 371 deaths. The total infant mortality was 8.1 per cent. Of the total deliveries included in this study there were 469 premature. This is equivalent to one in every 10 births. (The Boston Lying-In Hospital reported that premature births represent only 3 per cent of their total

TABLE I—INFANT DEATHS UNDER ONE YEAR OF AGE IN PENNSYLVANIA

	No of cases 1931	Per cent 1931	No of cases 1932	Per cent 1932
Total deaths	11 879		10 103	
Prematures	2 886	24.3	2 697	26.6
Disease of early infancy	1 387	11.6	2 896	28.7
Pneumonia	2 185	18.3	1 676	16.5
Gastro enteritis	1 460	12.2	1 034	10.2
Malformations	1 378	11.6	1 152	11.4
	9 296	78.0	9 405	93.4

The same can be said also of malformations and other diseases of early infancy, while substantial reductions have been made in the death rates of pneumonia, gastro intestinal and other diseases occurring in the first year of life during this same period. It is because of this high mortality that our interest in the problem of the premature has been stimulated.

According to the records presented in this paper, prematurity was the cause of 68 per cent of the total deaths occurring during a 27 month period at the Philadelphia Lying-In Hospital. At the Boston Lying-In Hospital prematurity accounted for 65 per cent of the newborn mortality. In the past few years the gross premature mortality at the Boston hospital was reduced from 60 to 25 per cent. Some of this decrease in mortality is undoubtedly due to this hospital's splendid system of

deliveries. Of the 469 premature infants studied, 253 died. This is 68 per cent of the deaths. Of this number, 216 babies lived showing that we were able to save 46 per cent of the premature births or in other words, our premature mortality was 54 per cent.

Only cases delivered in our hospital are considered in these statistics. A good many of this group were extremely small infants and very much premature. According to the regulations of the Bureau of Vital Statistics of our State, all infants who have reached the legal age of viability, which is four and one half months' term and death occurs, must have a death certificate made out for them. Only premature infants are included in this group. Any full term baby, although very definitely immature and whose weight corresponded to many premature infants was discarded. Again only babies who were more than two weeks premature were con-

sidered. This stand was taken because we realized that it is very difficult to be exact in determining the age of the child and felt that a leeway of two weeks should be considered in selecting our cases.

These infants were handled in our regular nurseries or in small adjoining rooms. A rotating nursing staff took care of the babies. None of the rooms was air-conditioned, although the temperature of the rooms themselves was under thermostatic control and could be fairly uniformly regulated. Our methods of regulating humidity were definitely inadequate. It was difficult to get our humidity above 25 per cent. A modified hot-bed enclosed on all sides except the top and heated by electric lights was used. Unless they were closely watched, there was considerable fluctuation in the temperature of these hot-beds. Basins of water were placed underneath the mattresses near the lights in order to increase the moisture in the air.

CAUSE OF PREMATUREITY.—In a good many previous reports, notably that of

of the prematurity could be discovered, but no doubt, strains, overwork, sexual intercourse, or emotional upheavals were the causes of the premature births. Of this latter group in which no cause of prematurity could be found, 126 of them lived and 70 died.

THE INFLUENCE OF GRAVIDA.—It has been frequently expressed in the writings of men who are dealing with prematurity that multiparous mothers usually give birth to large children, even though premature, and that the babies are more easily saved than those of primiparous mothers. In this group of cases (Table IV), it is very interesting to note that the lowest mortality occurred in primiparous mothers and was 47 per cent. In premature babies of the second pregnancy, 51 per cent died; of the third pregnancy, 53 per cent; of the fourth pregnancy, 54 per cent; of the fifth pregnancy, 67 per cent; and of the sixth and later pregnancies, 79 per cent. As the number of previous pregnancies increased, the mortality of the premature

Hess, multiple pregnancies has been the greatest single cause of prematurity. In this group of cases (Table III), syphilis heads the list as the probable cause in 18 per cent. Toxemia of pregnancy comes next with 12 per cent; multiple pregnancy caused 10 per cent; premature separation of the placenta caused 5 per cent; placenta praevia caused 1.9 per cent. Cardiac, pulmonary, kidney, acute respiratory infections, and myoma of the uterus were rather insignificant as causes of prematurity in this group. Injury of some kind to the mother, such as falls or blows, caused 2 per cent of the premature births. There were 196 cases in which no definite cause

infants likewise increased. In checking over the average birth weight of the premature infants born of primiparous mothers, it was noted that the average birth weight of those who died was the same as for the whole group. The average birth weight of babies born of primiparous mothers of those who lived was likewise the same as the average birth weight of the entire group.

An attempt was made to see what effect the age of the mother has on the death rate of premature infants. Three groups were studied (Table V). The first group in which the mother was under 20 years of age showed a mortality of 46 per cent;

in the second group of mothers between 20 and 30 years, the mortality was 52 per cent, in the third group in which the mother was over 30 years of age, the mortality was 56 per cent. It was rather difficult to draw conclusions regarding the influence the age and gravida of the mother have on the premature infant mortality.

THE EFFECT OF DELIVERY—It was rather a surprise in studying the effect of delivery (Table VI) on the deaths of

TABLE VI

Section	88	1	1.1

premature infants to find that our lowest mortality rate occurred in babies who had been delivered by forceps. This probably can be explained by the fact that pressure on the infant's skull against rather rigid perineal muscles can be reduced by the application of forceps. The second lowest death rate in this group was in the cases delivered by cesarean section, the third lowest were those delivered spontaneously, and the highest in those delivered by breech. This corresponds very closely to what happened when a study was made of the total mortality during the same period. In those delivered by forceps, the mortality rate was lowest and in those delivered by breech, the mortality rate was highest. In a group of cases that were studied to determine the incidence of cerebral hemorrhage as related to the type of delivery, forceps stood third on the list while breech deliveries again stood last.

The length of labor (Table VII) in its relationship to premature infant mortality does not seem to enter very much into the cause of death, and yet the author feels sure that it does. The mortality rate of babies who were delivered after five

hours or less of labor was 47.3 per cent while in those delivered in five hours or more, the mortality was 53.2 per cent. The length of labor, particularly the second stage, undoubtedly has a greater tendency to be the cause of intracranial hemorrhage than when the second stage of labor is cut short by the appropriate application of forceps. It is entirely possible that the delivery of the infant by means of forceps to lessen the second stage of labor has had a great deal to do with

keeping the mortality record low in this respect.

IMPORTANCE OF BIRTH WEIGHT—Numerous observers have shown from time to time that the mortality of premature infants is inversely proportional to the birth weight of the infant (Table VIII), that is, the lower the birth weight, the greater is the mortality rate. In this group of cases studied, all babies under 2 lb died, 95 per cent of those under 3 lb died, 77 per cent of those under 4 lb died, 46 per cent of those under 5 lb died, 20 per cent of those under 6 lb died, and all premature infants over 6 lb lived. In this group that is studied, if we eliminate all babies under 2, 3 and 4 lb, respectively, our mortality rate drops to 49, 40, and 32 per cent, respectively.

During the last two months of pregnancy, it is known that infants average about one ounce gain in weight per day. With each additional ounce added to their weight the infant has a much better chance of surviving after birth. This is shown very definitely when the term of the child was considered (Table IX). In reviewing records to collect these data, many times it was difficult to determine the exact term of the infant. The last menstrual flow,

quickening, and the measurements of the position of the uterus are employed. No attempts were made to estimate the fetal age by the body measurements, length, foot length, head circumference, or by a study of ossification centers. It is noted that all babies under 5 months' term died. Likewise, in all babies under 6 (calendar

TABLE IX.—TERM OF CHILD

8 to 9 months.....	69	29

months' term died; 96 per cent of all babies under 7 months died; 59 per cent of those under 8 months died; and 29 per cent of those under 9 months died. This emphasizes again the importance of trying to have the mother carry the infant as long as is possible or safe for both mother and child.

Dr. Clifford of Boston has devised a very clever method of measuring the child's head, intra-utero by means of the x-ray to determine more exactly the fetal age. This method is particularly useful in elective deliveries, where the delivery can be postponed to allow further development of the infant.

The average birth weight of the 216 babies who lived was 5 lb. 3 oz., and of the

253 who died it was 3 lb. (Table X). The average loss in weight of the 216 who lived was 6.9 oz. The percentage loss in weight was 8.3 per cent. This loss in weight corresponds very closely with several large groups studied in which the percentage loss of weight was between 7 and 8. Of the 216 babies who lived, 113, or 52 per cent, regained their birth weight within 21 days. It is to be remembered that the normal full-term child of average weight usually regains its birth weight between six and twelve days.

THE CAUSE OF DEATH.—It is rather difficult at all times to assign a proper cause of death. Of the 253 premature infants who died, 126 were believed to have been dead before delivery, and 3 of them died during delivery—all of intracranial hemorrhage. Of this group, 124 died after delivery. In this last group of 124 (Chart I), 62 of them lived 12 hours or under; 13 lived from 12 to 24 hours; 9 lived 2 days; 5 lived 3 days; 2 lived 4 days; 4 lived 5 days; 8 lived slightly over 1 week; 1 lived slightly over 1 month; 3 lived for about 2 months. In 19 of these cases, the exact length of life was not known. This last group constitutes the emergency cases, some of which were delivered in taxicabs en route to the hospital, a few in the waiting room and preparation rooms of the Hospital where observations as to the length of life could not be made.

In studying the causes of death (Table XI) we find that syphilis alone heads the

list as the cause of 50 deaths; toxemia, either alone or combined with syphilis, was the cause of 37; premature separation of the placenta was the cause of 16;

placenta praevia caused 6 deaths, intracranial hemorrhage caused 19 deaths, injury to the baby of a nature other than intracranial hemorrhage caused 5 deaths, pneumonia caused 13 deaths, atelectasis 14, malformations, 11, narcosis, 2, polyhydramnios, 2, placental infection, 1, nephritis, 3, a tightly wrapped cord about the neck, 1, and abortion inflicted by the mother on herself, 3. In 3 cases there was a history of chronic and repeated miscarriages. It was impossible to determine the cause of death of 38 babies who died before delivery. However, 27 of this group were under 3 lb in weight. Likewise, there were 28 babies who died after delivery, in which the causes were not determined. Twenty-six of this group were under 3 lb in weight. One hundred forty-nine autopsies were performed on this group of 253 in which a careful search was made of the entire body in an attempt to discover the cause of death. Such autopsy examinations, however, fail to disclose any lack of physiologic function and more than likely miss a great many structural defects unless extensive microscopic studies of all organs are made.

Syphilis is one of the big problems we are confronted with in trying to prevent prematurity and in the successful management of the case after birth. Of the cases of syphilis in this group, 44 were treated prior to birth, 24 of them died, making a mortality of 54.5 per cent. There were also 44 untreated cases with 36 deaths, making a mortality of 81.8 per cent. This finding has been demonstrated on a number of occasions in other clinics.

The rôle that infection plays as the cause of premature deaths is well known, but in this group of cases, apparently it did not play much part, particularly so, if the 50 cases of syphilis were eliminated. The 13 cases of pneumonia that were proved and one case of generalized sepsis in the child due to placental infection is a small number of deaths due to infection.

PATHOLOGY IN LIVING BABIES—When observations were made as to the extent of pathology found in the premature who lived (Table XII), again it was found that infection did not play a very great rôle. There were 3 cases of thrush, 1 case of impetigo, 4 cases of diarrhea, 3 cases with acute rhinitis, 4 cases with intracranial hemorrhage, 1 case with gonorrheal ophthalmia, 1 baby had a large abscess of the thigh due to a sloughing angioma, 1 case

of inguinal hernia which had become incarcerated, could not be reduced, and operation was performed, there were 3 cases of pylorospasm, and 1 case of pyloric stenosis. The latter was a rather unusual case, in that the child was 7 months' term, had a stormy start in life, did very well on treatment, remained in the hospital 2 months and 2 weeks after discharge, when it was 2 weeks over full term, developed a typical pyloric stenosis, and was operated on successfully. Forty seven of the babies who lived developed asphyxia with recurrent cyanotic attacks, sometime during their stay in the hospital, and a good many of the babies who lived only a short time also developed cyanosis. In this group of 216 who lived, 147 were delivered while the mothers were under anesthesia, ether being the chief anesthetic used.

DIGESTIVE DISTURBANCES—Just as other systems of the premature child are inadequate to meet physiologic needs, so is the digestive system and in many of these cases, the digestive capacity is decidedly limited. Some of the first indications of disturbance of the gastro-intestinal tract are the refusal of food, slight vomiting, with a change in the character and number of stools. Careful attention to the feeding during the first ten days will often prevent these digestive difficulties. It has been our experience that these so called minor disturbances dare not be ignored, for they are frequently followed by persistent vomiting, profuse diarrhea, rapid loss of weight, fever accompanied by de-

hydration, and disturbance of the acid-base balance.

Some of these babies undoubtedly have difficulty outside the gastro-intestinal tract. Autopsy performed on such cases might show a pneumonia or some other serious infection. While the child is living, it is difficult to decide whether the digestive upset is a primary factor, or whether it is secondary to some other pathologic change.

BLOOD CHANGES.—Weekly blood counts on premature infants disclose the fact that there is a more rapid and greater fall in the hemoglobin (Chart III) and red cells (Chart II) in premature babies than occurs in normal full-term infants. It is quite common for the red cells to fall two million in six to eight weeks' time, and for the hemoglobin to decrease by 8 to 10 gm.

Chart II—Hemoglobin

The shortest stay of any in the hospital was 9 days. There were 7 in this group. The longest stay in the hospital was 171 days. This was the child who had the strangulated hernia when it was 2 months old, followed by a successful operation and stormy convalescence. One hundred and thirty-four were in the hospital from 10 to 20 days; 22, from 20 to 30 days; 23, from 30 to 40 days; 17, from 40 to 50 days; and 13, for over 50 days.

FEEDING.—One of the most important factors in the care of the premature infant is that of feeding. This includes not only the choice of formula, but the amount, method, and frequency of feeding. It can be safely said that most of the premature babies should not nurse at the breast, while at the same time,

Chart III—Red cells.

in the same length of time. The cause of this sudden and rapid drop of hemoglobin and red blood cells may be due to two factors: the bone marrow and other blood-forming organs, because of their immature development are unable to meet the demands made for new blood; the supply of iron stored in the body or contained in the food is usually inadequate for the needs of the premature infant. To a certain extent, the development of this anemia can be checked by the giving of fairly large doses of iron combined with minute doses of copper. It seems necessary to supply this iron in some inorganic form.

The length of time the premature infant stays in the hospital (Table XIII) requiring close nursing supervision and medical attention adds a great deal to the overhead costs of the maternity hospital.

breast milk is the food of choice. Of the 216 cases who lived, 166 were fed breast milk. Complementary feeding was needed in 88 of this group. As a general rule, nothing was given to these premature infants during the first 6 to 12 hours after birth. At the end of this period, boiled water with a few drops of whisky was given at intervals. During the past year, attempts have been made to utilize the hydrating solution as suggested by Kugelmass, during the first 2 or 3 days after birth. Our experience leads us to the conclusion that this is readily taken, that vomiting is much less, and that dehydration is successfully combated. In this group, at the end of 12 to 24 hours, depending upon the size and condition of the baby, breast milk was started. They were usually fed every 2 hours, giving

from one to four drams at every feeding, depending upon the individual case. When breast milk was not available, skimmed lactic acid milk was used in most of these cases. The combination of breast milk, and skimmed lactic acid milk as complementary feeding seemed to be quite successful in the majority of cases. When it was necessary to use whole lactic acid milk particularly in the absence of breast milk, distention of the abdomen, and rather frequent, small, formed, foul stools resulted, with irritation of the buttocks and considerable tendency to vomiting. A few of these babies were fed on formulas of evaporated milk, sweetened condensed milk was used in a few cases, several forms of dried milks also were used. The dried milk which apparently is best suited for premature infants is Similac. At the present time, most of our premature infants who are on formulas are given Similac and we believe results will be better than in the present group reported. Whenever possible, babies were fed with a bottle, a few of them needed the Breck feeder, and nearly all the small babies had to be fed by catheter, passed through the mouth at each feeding.

Mothers who have given birth to premature babies frequently are slow to establish lactation and, when established, it is usually difficult to maintain. Every effort was made to stimulate the secretion of breast milk and to maintain it by use of the electric breast pump, by hand expression, and by alternating hot and cold compresses, with gentle massage of the breasts. A great deal of the success of this procedure depends on the intelligence and faithfulness of the nursing supervisors.

CONCLUSIONS

- 1 A study of 469 premature infants covering a 27-month period is submitted.
- 2 The cause of prematurity is difficult to assign. More attention needs to be placed upon finding the cause in order to prevent these early births.
- 3 The relation of birth weight, term, gravida of the mother on premature mortality is given.
- 4 It appears that forceps delivery is the safest method in such cases.
- 5 Close attention to temperature and humidity factors is necessary.
- 6 Breast milk is the food of choice for premature infants.

A PLAN TO EVALUATE INDEPENDENTLY SEROLOGIC PROCEDURE FOR THE DIAGNOSIS OF SYPHILIS IN THE UNITED STATES

Since the serologic conferences at Copenhagen and Montevideo, there has been an increased interest in the relative value of serologic tests for the diagnosis of syphilis. At these conferences the test of only one serologist of the United States was presented for consideration. There are a number of excellent serologists in this country, many of whom have described original modifications of the complement fixation and precipitation tests for syphilis. It is felt that the tests of these workers merit consideration.

The United States Public Health Service is cooperating with the American Society of Clinical Pathologists in the drafting of a plan to evaluate independently serologic procedure for the diagnosis of syphilis in this country. Briefly, the plan contemplates the collection of specimens of blood from at least 1,000 individuals and the distribution of comparable specimens to the laboratories of serologists who have described an original modification of a complement fixation or precipitation test for the diagnosis of syphilis. The donors of the specimens will be carefully selected so as to measure both the specificity and sensitivity of the serologic procedure. The sending of specimens to workers at considerable distance from the point of collection will be expedited by the use of the most modern transportation facilities while the delivery of specimens to nearby serologists will be delayed so as to

make the delivery time approximate that for those workers at the more remote points.

A committee of five members consisting of two specialists in the field of clinical syphilology, two members of the American Society of Clinical Pathologists and one officer of the United States Public Health Service will organize the plan of study and after all laboratory reports have been submitted by participating serologists, will interpret the results on the basis of clinical findings. The collection of the specimens will begin about December 1, 1934 and a number of serologists will be invited to take part in the evaluation scheme.

It is possible that the name of some serologist who has described an original modification of a test for syphilis may have been inadvertently omitted. Any serologist desiring to participate will be extended an invitation upon presentation of suitable proof as to the originality of his modification of a serologic test. A brief description of the plan will also be sent to those workers who may be interested.

As a result of a "crusade" by a local newspaper, Utica has launched a campaign to eliminate ragweed and other plants responsible for hay fever and allied conditions.

DIAGNOSTIC VALUE OF ASPIRIN TEST IN RHEUMATIC CONDITIONS

HEINRICH F. WOLF, M. D.

Chief, Department of Physical Therapy, Mt. Sinai Hospital, New York City

In the issue of the NEW YORK STATE JOURNAL OF MEDICINE of September 15, 1933, the author published an article entitled "Aspirin Test to Determine the Advisability of Removal of Foci in Rheumatic Conditions." Due to lack of space all clinical data were omitted, but as a great deal of interest has been evinced in this paper, it is believed that its value would be enhanced by a brief report of clinical evidence in support of the statements set forth therein.

Before mentioning any case histories it is advisable to state that it has been the author's custom to give aspirin to patients suffering from rheumatic pains. The negative response to a dose of aspirin, that is, no influence on the pain, is the deciding factor in this test and governs recommendation for removal of foci. The author refuses to sacrifice a tooth or excise the tonsils if the patient is not relieved. If the test is positive, that is, if relief of pain is obtained, the presence of a streptococcus infection can be assumed, although the active focus may be located in other places than the head.

The following cases are taken at random: A patient in the dispensary had her teeth extracted and tonsils removed for acute pains without relief. A dose of aspirin had no effect but she was quickly relieved by atophan. The examination of the blood showed 6.5 mg. of uric acid.

We have observed many cases in the dispensary in whom such operations had been performed without result and in all of them the patient failed to respond to aspirin. Every one of these patients could have been spared the ordeal.

The following cases will illustrate the diagnostic value of the aspirin test.

Some years ago we treated a girl for tuberculosis of the hip joint which eventually healed with shortening of the leg. She came to the clinic later complaining of severe pain in the hip which had lasted for some time. We gave her aspirin and the pain disappeared at once. The x-ray showed a perfectly healed tuberculosis of the joint. Further examination revealed that tonsils and teeth were infected and an operation cured her from her pain in the

A patient, 57 years old, complained severe pain with restriction of motion the hands, shoulders, the vertebrae, and legs. He had no teeth but reacted to aspirin with complete subjective relief. A radiograph of the toothless jaw revealed a number of infections in the jaw bone where infected teeth had been extracted without curettage. The abscesses were operated by Dr. Ralph Brodsky and a pure culture of *Streptococcus viridans* was obtained. The patient improved steadily after the operation.

A woman of 60 complained for 10 years of severe pain in the right sacro-iliac region. A swelling, very tender to touch was found there and the roentgenogram showed indistinct contours of the sacro-iliac junction at that spot. She had no teeth. One dose of aspirin gave prompt relief. A roentgenogram of the teeth showed 3 buried roots and a large abscess on the left side of the lower jaw. The patient was operated and began to improve immediately. Within two months the pain had disappeared completely.

Many such cases on the positive as well as on the negative side could be quoted but only mention need be made that those cases which had active foci, although heat treatments produced nearly always exacerbation of the rheumatic symptoms, particularly the pain. This fact also is of great prognostic importance and a valuable guide for indications. We can say with reasonable certainty that a focus is active if after a course of treatment with heat procedures which should relieve the condition, an improvement is followed by an exacerbation. Many physicians are inclined to blame external factors, such as the weather, for it. The writer believes, however, that such exacerbations are due to the increased transportation of bacteria and toxins into the joints treated with hyperemia-producing modalities. This assumption has been extremely valuable in looking for foci.

Thus we may say that exacerbation after heat treatments indicate an active focus, relief by salicylates points to streptococcus infection, failure of relief indicates the necessity of looking for another

Atlanta's Experiment

Mark Twain said that "everybody is always complaining about the weather, but nobody does anything about it." A rural doctor in Georgia, at the convention of his State Medical Association, made a rather similar remark about the medical economic crisis. "All this talk about medical economics is just 'bull'," he declared. "We are not going to do anything about it. We meet, talk, go home, and cuss, and it is all the same." Medical societies pass resolutions that are published in the news papers, speakers flay the report of the Committee on the Cost of Medical Care, but much of the fire ends in smoke.

The physicians of one city, however, have decided that the policy of mere talk has gone on long enough. The medical men of Atlanta have had a committee at work on the matter for nearly two years, the committee has formulated a plan, the plan has been adopted, and on April 1 it was put into operation.

The Atlanta plan is based upon the minority report of the Committee on the Cost of Medical Care. The minority report, it will be remembered, recommended

a county medical society plan for furnishing complete medical care to persons in the low income bracket. It advised the furnishing of medical care by the individual physicians as they are at present organized in county societies, the plan to be kept under professional control, and financed by annual payments under a group arrangement. The plan, too, guaranteed the absolutely free choice of physician and was to include all or a large majority of the county medical society, with the funds administered on a nonprofit basis.

Such a plan places the responsibility for the medical care of the community squarely upon its organized physicians and bars control by lay corporations and insurance companies. The quality of the medical service is thus guaranteed and the possibility of unethical competition is removed because all the physicians of the community are included and the fee schedule is fixed. Solicitation of patients, underbidding for contracts, and other evils of ordinary plans are eliminated, and the essential personal relationship of doctor and patient is preserved.

It is upon this basis that the Atlanta physicians have built their plan, after nearly two years of careful study by their committee. They have organized the Fulton County Medical Relief Association, and out of 387 members of the Fulton County Medical Society, 268, or more than two-thirds, have indicated a desire to cooperate. Of the rest, some are indifferent, some more or less hostile, and "some few" irreconcilable.

The report to the Medical Association of Georgia, from which these facts are gleaned, points out that the new Association does not agree to furnish medical service to anyone, but simply agrees to pay the doctor who renders the service. Any co-operating member of the County Medical Society may respond to calls from the beneficiary members, or he may decline the call precisely as under the old plan.

Patients of low income may obtain medical care under this plan for \$1 initiation fee and \$1.50 a month. The privilege of membership is open to any white person in Atlanta and vicinity who is in good health, except drug addicts and alcoholics. To

keep the well-to-do from flooding in the income level of those who join is not to exceed \$75 per month for persons without dependents, \$125 per month for those with one dependent, \$135 for those with two, \$145 for those with three, and \$150 for those with four. Membership is limited to individuals. Separate membership may be carried for other members of the family. The Association is controlled by a board of five directors, all physicians, elected from the membership of the County Medical Society and serving without pay. Details are handled by a lay manager.

It is too early to forecast the fortunes of the venture, but the committee feels optimistic. It figures that the Association must have 5,000 beneficiary members on its rolls to ensure success, and 10,000 would be better yet. Physicians, too, must accept lower fees than are considered standard, and the County Society has adopted such a schedule upon the realization that, even if lower, it will produce a larger return from the same group than the old plan did.

Here, then, we have an honest effort to head off the threatening socialistic plans with a scheme that will preserve the essentials of present medical practice and ethics. It meets the regimenting plan with a doctors' plan. It meets any proposed or paper plan with a plan already in actual operation. It may not be the best one imaginable. If anyone can suggest improvements, so much the better. But if we can meet the socializers and regimentalists with well-based medical plans already adopted and in operation, then their fine-spun schemes and dreams will not have, if the expression may be pardoned, a Chinaman's chance.

The Modern College Girl

Almost every physician has somewhere among the families under his care certain young women, in college or of college age, who are showing the strain of modern life and are more or less of a problem to their parents and to themselves. Their natures seem to change in puzzling ways. They may adopt a hard and metallic exterior that no one can melt; they may plunge into a whirl of frivolity and sacrifice all the serious and sensible things of life; or they

may even throw all the old moral standards overboard to please the opposite sex and then discover too late that the opposite sex has lost all respect and regard for them. These are only a few of the psychological manifestations that make the young woman of to-day a problem.

A deep study of this matter has been made by Dr. Elizabeth G. Whitney, of Palo Alto, California, Consultant in Mental Hygiene of the Department of Hygiene and Physical Education for Women at Stanford University. In an able paper read before the American Student Health Association at Chicago, Dr. Whitney traced the feminine psychology from primitive times to the present, and drew upon her wide practical knowledge of the college girl to find that the root trouble is that she is under two strains, pulling her in opposite directions.

First of all, her nature is essentially womanly, maternal. She cares, she loves. she trains, she nourishes. She lives in the domain of the affections and emotions. From the dawn of time these qualities have held sway in her being, and she can no more rid herself of them than the leopard can change his spots. The man, on the other hand, is by nature fitted for doing and making. He goes forth to battle with the world as naturally as the fish takes to the water.

But in recent years woman has decided to invade man's field. She will make and do. She will fight the world. So our college halls are all aflutter with femininity. Our city offices frequently resemble a tea party. Studious? Yes. Efficient? Yes. But we find after a bit that a number of the young women show signs of cracking under the strain. Their nerves or their physical health begin to give way or they exhibit some of the puzzling peculiarities noted in the opening paragraph.

Why does this happen? The secret of it is that the girl can invade man's domain if she likes, but she cannot throw off the shackles that still bind her to her own nature. She is pulled in two directions. She is torn in one direction by the desire to be a man, or to do a man's work, and in the other by the basic instinct to be a woman. Is it a wonder, asks Dr. Whitney,

that the adolescent girl is confused in the melee, or that she shows the effect in unhappiness, adjustment problems, neurosis, and perhaps breakdown? Where the primitive or mid-Victorian girl moved with serenity and ease through her daily round, the modern girl is like an overstretched violin string, ready to snap. Foreign visitors observe this

It is true that the girl student often outdoes the boy, but it is at the price of hard driving such as the boy will not do. It is Dr Whitney's observation that the boy moves more familiarly and carelessly in his college life. He can neglect his work or plunge deeply into it, he is a fish swimming in his own element. The successful girl student, on the other hand, becomes obsessed by her lessons, works after midnight week in and week out, and loses all sense of the real values of life. Another girl will react in the opposite direction, drift aimlessly about, weep because she is "a complete failure," and threaten suicide over a bad report.

Torn by these warring forces, some girls give the picture of great insecurity and confusion with shyness, awkwardness, nervous habits, even hysterics. Another under the same strain will throttle her emotions with an iron hand, assume a glacial exterior, repel boy and girl friends, and pursue her solitary way. Both are resentful when they are summoned for psychological help, and Dr Whitney remarks with great acumen that neither one knows that she is suffocating a whole aspect of herself without which she cannot live. Both deny it, but when led to own up that they have and need feminine feeling, they astonish themselves by the wealth which comes welling up, and the new ease of their adjustments.

A darker picture is presented by the girl who has been misled by the flood of talk about sexuality to abandon woman's instinctive attitude and adopt the man's point of view. Man has still much of the primitive savage in him, and sexuality is to him often merely a sensation, while to the woman it is bound up with a hundred tender feelings. If, then, she tries to take the man's view, she outrages all the strong-

est impulses of her own nature, she finds her male "pal" has grown cold and indifferent, and she becomes hard, cynical, disillusioned, lacking in feeling, with no soul, because it has been paralyzed, with no respect for men, with no belief in the real value of anything. A reckless gayety covers a bitterness of despair.

What all these young women have forgotten is that they are women. They try to ignore or suppress what cannot be ignored or suppressed. The cure is for the girl just to be herself, to be a woman, to give a natural outlet to the feelings that fill her being as the waters fill the sea. She ought to have warm, intimate friendships with other girls, to make her social contacts on the impulse of her own heart, and not try to subordinate it to her work on her ambition. She should have many warm friendships with boys, too, guided by her unerring instincts and says this keen student of the feminine heart, "reserve her deepest love for the one man who can respond in kind."

A Favorite Quack Claim Punctured

Every quack who has some bogus cure to foist on the gullible public seems to try to poison his victim's mind against the medical profession. "The doctors are so conservative that they will not try any new remedy," declares the impostor, "they fight anything new, and a wonderful discovery like mine never has a chance." The doctors form "a ring," or "a trust," he avers, and they are so "hidebound" that they conspire together to boycott any new treatment or compound that might displace the old.

How ridiculous this claim is every doctor knows, of course, but half his patients do not know it, and in fact this libel is fed to the public every day by hundreds of montebanks who coin money out of it. And while the doctor knows that it is wickedly false, he cannot always offhand make a convincing reply. He knows that hundreds of proffered "cures" and "discoveries" are rightly rejected by the medical profession because they do not do what they claim, but he does not remember at the moment the hundreds of new remedies of real worth and value that are being adopted so rapidly that the ordinary physician can hardly keep up with them.

Far from being inhospitable to new ideas, medicine is alive with them, very much alive, so alive that great medical laboratories are swarming with countless investigators who experiment with everything on earth, in the earth, and under the earth, to cure the ills of man. The fact is that no discovery is too strange or novel to get a welcome if it can make good. A woman doctor with a full quota of feminine curiosity tries injecting a solution of ordinary methylene blue dye into the veins of rabbits with cyanide and carbon monoxide poisoning, and saves them. Now would-be cyanide suicides and victims of motor-exhaust fumes are snatched back from the jaws of death by something originally intended merely to give objects a cerulean tint. That is medical hospitality to new remedies.

Again, a doctor in Mexico, experimenting with bacteria, announces that he has discovered a "bacteriophage" that eats the enemy bacteria with such an appetite that cultures of them disappear entirely. This certainly sounds like a page from the Arabian Nights or Alice in Wonderland. The "hidebound" doctors would surely hoot this out of court if the quacks are right about them. But nothing of the sort happens. The doctors have welcomed the find with open arms, and the bacteria eater has promptly been put to work.

A new remedy may be as common as air or sunshine. It may be something you can buy at the market. From time out of mind the doctors were baffled by pernicious anemia, and then someone found that all you had to do was to order plenty of liver from the meat man and eat it in generous helpings, and the fatal malady was fatal no more. Where was the "conservative" profession that rejected everything new? Nowhere, except in the imagination of the quack and his victim. Everything is welcomed that will aid the great battle for health. The liver's neighbor and collaborator, the stomach, is also good for anemia, and we find the medical manufacturers slicing, drying, and grinding hogs' stomachs into a palatable powder that restores the pallid anemic sufferer to ruddy health. Hogs' stomachs! Is this in China? No, in "conservative" America. Yet the quack would have the public believe that the doctors rejected his own vile stuff out of "conservatism" or "jealousy."

Medicine, too, welcomes everyone who can help. The electric knife, that can do

many operations formerly impossible, was developed with the aid of the electrical engineers. The public may be very sure that if Mr. Quack had anything of value it would have been adopted by the profession with enthusiasm. Let us suppose that someone was crazy enough to suggest abolishing pain by pulling out the nerves that felt it! Wouldn't the doctors just naturally send anyone like that to the asylum? Well, that is exactly what was suggested, and that is what is being done in the treatment of angina pectoris, spastic paralysis, and many other ailments where the nerves have become only sources of mischief. Was it one of the brilliant quack geniuses who found that some kinds of insanity could be cured by giving the patient malarial fever, and did he keep on experimenting until he found that an artificial fever could be produced by an electrical machine to do the same thing? Hardly. It took the "backward" medical men and the orthodox electrical engineers to do that. Offhand, would you say it was the doctors or the grannies of the Kentucky mountains who use mistletoe and watermelon-seeds for high blood pressure? Oh, you know, of course; but ask any layman and see what answer you get.

The truth is that it is the doctors themselves who are trying a thousand things for all the ailments that have refused thus far to yield to their skill. For one quack remedy that is found worthless and rejected, the experimenters in the laboratories throw aside a hundred of their own. But they keep on trying. They do not take the experiment that failed and try to foist it on the public under a smoke screen of abuse of honest practitioners. They work on, perhaps for years, until the real remedy is found, in the sure knowledge that the entire profession, the world around, will adopt it for the welfare of all humanity.

The facts sketched here are well-known to every intelligent physician, but may not be at the tip of his tongue at a time when it is desirable to answer the claims of the medical charlatan. They will be found ably and interestingly presented, with many more, in a new volume by Dr. Edward Podolsky, entitled, "Medicine Marches On," published by Harpers. Medicine is marching. It is not standing still, and it is not looking backward. Its face is toward the future, and it welcomes everything good that it finds in its path.

SCIENTIFIC PROGRAM OF THE TWENTY EIGHTH ANNUAL MEETING

THIRD DISTRICT BRANCH

MEDICAL SOCIETY OF THE STATE OF NEW YORK

Potts Memorial Hospital, Livingston, N Y

Wednesday, September 19 1934, 10 00 A M Daylight Saving Time

MORNING SESSION

The Columbia County Department of Health"

Organization—

William D Collins, M D, Hudson, President, Columbia County Board of Health

Relation to the Physician—

Frank C Maxon, M D, Chatham, President, Columbia County Medical Society

A Modification of the Detroit Plan in Administering Public Health—

Louis Van Hoesen M D Hudson, Commissioner of the Columbia County

Department of Health

Discussion by James F Rooney, M D, F A C P Albany

Rehabilitation of the Tuberculous at the Potts Memorial Hospital, Livingston, Columbia County, New York

losis, University of Pennsylvania Philadelphia

Harry A Pattison, M D, Director Potts Memorial Hospital

Leonard Marion Neisen M D Resident Physician, Potts Memorial Hospital

Luncheon and Introduction of Guests

AFTERNOON SESSION

Election of Officers

'Address by the President, Medical Society of the State of New York"

Arthur J Bedell, M D, Albany

Some Theories and Facts Regarding the Treatment and Prognosis of Early Syphilis"

Earl D Osborne M D, Buffalo Professor, Dermatology and Syphilology, University of Buffalo School of Medicine

The Potts Memorial Hospital is located at Livingston Columbia County on Route 9 eight miles south of Hudson

PROGRAM OF THE ANNUAL MEETING

SIXTH DISTRICT BRANCH,

MEDICAL SOCIETY OF THE STATE OF NEW YORK

Central High School Building, Cortland, New York

September 26, 1934 at 9 30 A M, Daylight Saving Time

9 20 Address of Welcome Dr W A Wall, Cortland, N Y, President, Cortland County Medical Society

9 30 Syphilis of the Central Nervous System—Dr Hugh S Gregory, Binghamton, N Y

Discussion Dr Eugene E Bauer, Owego, N Y

Dr Orin Q Flint, Delhi, N Y

Dr Stewart Piper, Elmira, N Y

10 00 Traumatic Surgery Essentials in Prevention and Cure of Disabilities—Dr Martin B Finkler Ithaca, N Y

Discussion Dr Harry Fish, Waverly, N Y

Dr Thomas F Manley, Norwich, N Y

10 30 Treatment of Pneumonia—Dr Russell L Cecil, New York City

Discussion Dr Clifton H Berlinghof, Binghamton, N Y

Dr Allen W Holmes Watkins Glen, N Y

11 00 Surgical Management of Carcinoma of the Rectum and Rectosigmoid Motion Pictures—Dr Claude F Dixon, Mayo Clinic, Rochester, Minnesota

Discussion Dr Guy S Carpenter Waverly, N Y

Dr Ross G Loop Elmira N Y

12 00 Luncheon—Address The Journal of the Medical Society of the State of New York—

Dr Arthur J Bedell Albany N Y, President, Medical Society of the State of N Y

2 00 The Tragedy of Appendicitis—Dr Donald Guthrie, Sayre, Pa

Discussion Dr Arthur W Booth Elmira, N Y

Dr James Greenough Oneonta N Y

2 30 Treatment of Bacterial Endocarditis—Dr Ronald L Hamilton, Sayre, Pa

Discussion Dr George Mackenzie, Cooperstown N Y

Dr Norman Moore, Ithaca, N Y

3:00 Intestinal Obstruction—Dr. Wm. D. Johnson, Batavia, N. Y.

Discussion: Dr. Dwight G. Dudley, Endicott, N. Y.

Dr. Wm. H. Hobbs, Binghamton, N. Y.

Dr. Frank J. McCormick, Ithaca, N. Y.

3:30 The Technique of Obstetrical Forceps—Dr. Wm. T. Getman, Buffalo, N. Y.

Discussion: Dr. Herbert W. Fudge, Elmira, N. Y.

Dr. John W. Judd, Ithaca, N. Y.

Sessions will start promptly.

The Ladies will be furnished transportation from the High School Building to the Cortland Country Club where luncheon will be served. Price \$1.00. Following luncheon there will be cards and golf.

TWO OLD NEW YORK HOSPITALS JOIN FORCES ON SEPTEMBER FIRST

New York Post-Graduate and Old Skin and Cancer Hospital Boards Reach Agreement

Announcement of an affiliation between the New York Post Graduate Medical School and Hospital of Columbia University and the Stuyvesant Square Hospital, better known as the New York Skin and Cancer Hospital, was made on August 30, 1934, following a series of special meetings of the Boards of the two institutions.

In making the joint announcement for their respective institutions, Mr. Allen Wardwell, Chairman of the Executive Committee of the New York Post-Graduate Hospital, and Mr. Charles C. Harris, President of the Stuyvesant Square Hospital, stated that the pooling of the resources of the two institutions and the incidental economy in operation would make it possible to carry out more fully the purposes of each, not only with regard to research and treatment in the fields of cancer and diseases of the skin, but more particularly, the program for post-graduate medical education and service to the public generally.

According to the terms of the agreement between the two institutions, which goes into effect tomorrow, September 1st, it is provided that the identity of the Stuyvesant Square Hospital shall be maintained, and the membership of the Board of Directors of the Post-Graduate Hospital extended to include members of the present directorate of the Stuyvesant Square Hospital.

The Stuyvesant Square Hospital retains control of its capital funds, including any funds subsequently received by gift or bequest for maintenance or endowment of beds, while the Post-Graduate Hospital takes over the management and maintenance of buildings and equipment and the general administration of the hospital, funds for which are provided from the income of the Stuyvesant Square Hospital.

The professional staff of the Stuyvesant Square Hospital will be continued, according to the announcement, an invitation to its doctors to accept positions on the attending staff of the New York Post-Graduate Hospital having been already extended by the Board of Directors of the latter institution.

Both the Stuyvesant Square and the Post-Graduate Hospitals were founded in the same year—1882—and are pioneers in their respective fields, both having careers distinguished for their service to the public. Stuyvesant Square is America's oldest cancer hospital, specializing in the study and treatment of patients suffering from cancer and diseases of the skin. Post-Graduate was the first exclusively graduate school of medicine in the world, and the teaching facilities of its

general hospital are available only for the graduate physician.

The properties of the two affiliated institutions are contiguous, occupying the entire two-block frontage on Second Avenue between 19th and 21st Streets and extending, in the northern block, almost through to First Avenue. The two institutions have long worked in a friendly relationship so that this affiliation in the interest of both, comes as a logical step, not only making for more economical operation through the avoidance of duplication of activity and overhead, but by their inter-dependence making it possible to materially increase the quantity, as well as the quality, of their effort.

In addition to its work in the field of cancer, the Stuyvesant Square Hospital maintains the largest skin clinics in the country and when combined with those of the Post-Graduate Hospital, it is expected the affiliated institutions will become the foremost center for study and treatment of cancer and diseases of the skin.

The administration of the consolidated institutions will be supervised by a board of directors that will include the Post-Graduate Hospital board and members of the present board of the Stuyvesant Square Hospital. The directors of the New York Post-Graduate Medical School and Hospital are James F. McKernon, M.D., Honorary President, Arthur F. Chace, M.D., President, Allen Wardwell, Edgar H. Boles, William V. Griffin and Dave Hennen Morris, Vice Presidents, Robert E. Allen, Treasurer, Edward M. Townsend, Secretary, W. Vincent Astor, James Cox Brady, Nicholas Murray Butler, Henry Dwight Chapin, M.D., Thomas Crimmins, Robert C. Hill, Ludwig Kast, M.D., Charles S. McVeigh, Robert G. Mead, Karl Reiland, D.D., George T. Slade, Ralph S. Stubbs, Martin Taylor, George M. Thomson, George A. Vondermuhl, and James P. Warburg. Dr. Willard C. Rappleye is Dean of the Medical School and Dr. T. Dwight Sloan, Superintendent of the Hospital.

The present board of the Stuyvesant Square Hospital includes: Charles C. Harris, President, C. Forrest Butterworth, Jr., Secretary, Harris A. Dunn, Treasurer, James G. Blaine, John Howes Burton, Mrs. Samuel Adams Clark, Charles M. Connel, Richard G. Croft, Leonard J. Cushing, George Barton French, John Vosburgh Irwin, Frederick M. Johnson, George MacDonald, Winchester Noyes, John Reid, Jr., Franklin Simon, Richard A. Strong, Charles Seymour Whitman, and J. Edwards Wyckoff.

Medicolegal

LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

Revocation of Physician's License—Unprofessional and Dishonorable Conduct

A decision recently rendered by the highest Court of one of the mid-Western States is an excellent example of progress that is being made to rid the medical profession of its unfit and unworthy members.

A certain L. had received a license to practice medicine and surgery, and during the year following, after notice and hearing upon charges made, the state board of health revoked his license, under the following provisions of the Medical Act of the State:

"The board may refuse to license individuals of bad moral character, or persons guilty of unprofessional or dishonorable conduct, and they may revoke licenses, or other rights to practice, however derived, for like causes, and in cases where the license has been granted upon false and fraudulent statements, after giving the accused an opportunity to be heard in his defense before the board as hereinafter provided. Habitual drunkenness, drug habit or excessive use of narcotics, or producing criminal abortion, or soliciting patronage by agents, shall be deemed unprofessional and dishonorable conduct within the meaning of this section."

The record of L. which was before the Court is a most amazing one, and it is necessary to summarize it at some length.

After he received his preliminary education in the New York City public schools he had taken a premedical course at a recognized medical school in Brooklyn followed by a year and a half of medicine at one of the leading medical schools in Manhattan. He realized that he was about to fail at the latter institution and with several others in the same predicament entered a medical college in the state where he eventually obtained his license. After spending two years there he graduated. The following year he took the medical examination in that State, M., but he failed to pass. For the two years following he obtained employment at a dispensary in the State of M. After that, L. returned to New York, and although not licensed to practice, engaged in medical work as an assistant to a certain doctor in Brooklyn.

As his next step in trying to obtain a license he considered practice in the State of I. He learned that the licensing board of that State looked with disfavor upon medical schools such as the one from which he had graduated, and was invested with discretion as to the admission of graduates from such schools. He was referred by a friend to a certain Dr. K. in New York City who was reputed to have contacts with the I. State Board, and who might be able to arrange that he could be admitted for examination in that State. He approached Dr. K. and was informed that for \$2,000 the matter could satisfactorily be arranged. L. was unable to raise that amount of money at the time.

Some time later through Dr. K. he made the acquaintance of a certain B. who resided in the State of I. and entered into an elaborate scheme to obtain licenses in I. for himself and several other Eastern men. The arrangement agreed upon was that B. was to obtain permission for L. to take the state examinations as his compensation for bringing to B. the money, at six to eight hundred dollars each, which was to be used to obtain licenses for the other Eastern men to practice in the State of I. The money was paid over and purported licenses were delivered to L. for each of the "candidates." It later developed that the said licenses turned out to be forgeries and the "candidates" found themselves to be without any authority to practice medicine in I. At least \$2,500 changed hands during the deal. L. himself received his expenses, out of the bribery money, and whether he received any other part of the money is not clear.

After the fake licenses had been delivered, L. attempted to arrange through B. to obtain as his reward the privilege of taking the examination. He found that obstacles were in his way which B. failed to remove, and finally he left the State of I. and abandoned his scheme to obtain admission to practice there.

About a year later he was arrested and indicted for his part in the conspiracy. He and certain others involved were tried

According to the terms of the agreement between the two institutions, which goes into effect tomorrow, September 1st, it is provided that the identity of the Stuyvesant Square Hospital shall be maintained, and the membership of the Board of Directors of the Post-Graduate Hospital extended to include members of the present directorate of the Stuyvesant Square Hospital.

The Stuyvesant Square Hospital retains control of its capital funds, including any funds subsequently received by gift or bequest for maintenance or endowment of beds, while the Post-Graduate Hospital takes over the management and maintenance of buildings and equipment and the general administration of the hospital, funds for which are provided from the income of the Stuyvesant Square Hospital.

The professional staff of the Stuyvesant Square Hospital will be continued, according to the announcement, an invitation to its doctors to accept positions on the attending staff of the New York Post-Graduate Hospital having been already extended by the Board of Directors of the latter institution.

Both the Stuyvesant Square and the Post-Graduate Hospitals were founded in the same year—1882—and are pioneers in their respective fields, both having careers distinguished for their service to the public. Stuyvesant Square is America's oldest cancer hospital, specializing in the study and treatment of patients suffering from cancer and diseases of the skin. Post-Graduate was the first exclusively graduate school of medicine in the world, and the teaching facilities of its

general hospital are available only for the graduate physician.

The properties of the two affiliated institutions are contiguous, occupying the entire two-block frontage on Second Avenue between 19th and 21st Streets and extending, in the northern block, almost through to First Avenue. The two institutions have long worked in a friendly relationship so that this affiliation in the interest of both, comes as a logical step, not only making for more economical operation through the avoidance of duplication of activity and overhead, but by their inter-dependence making it possible to materially increase the quantity, as well as the quality, of their effort.

In addition to its work in the field of cancer, the Stuyvesant Square Hospital maintains the largest skin clinics in the country and when combined with those of the Post-Graduate Hospital, it is expected the affiliated institutions will become the foremost center for study and treatment of cancer and diseases of the skin.

The administration of the consolidated institutions will be supervised by a board of directors that will include the Post-Graduate Hospital board and members of the present board of the Stuyvesant Square Hospital. The directors of the New York Post-Graduate Medical School and Hospital are James F. McKernon, M.D., Honorary President, Arthur F. Chace, M.D., President, Allen Wardwell, Edgar H. Boles, William V. Griffin and Dave Hennen Morris, Vice Presidents, Robert E. Allen, Treasurer, Edward M. Townsend, Secretary, W. Vincent Astor, James Cox Brady, Nicholas Murray Butler, Henry Dwight Chapin, M.D., Thomas Crimmins, Robert C. Hill, Ludwig Kast, M.D., Charles S. McVeigh, Robert G. Mead, Karl Reiland, D.D., George T. Slade, Ralph S. Stubbs, Martin Taylor, George M. Thomson, George A. Vondermuhl, and James P. Warburg. Dr. Willard C. Rappleye is Dean of the Medical School and Dr. T. Dwight Sloan, Superintendent of the Hospital.

The present board of the Stuyvesant Square Hospital includes: Charles C. Harris, President, C. Forrest Butterworth, Jr., Secretary, Harris A. Dunn, Treasurer, James G. Blaine, John Howes Burton, Mrs. Samuel Adams Clark, Charles M. Connfelt, Richard G. Croft, Leonard J. Cushing, George Barton French, John Vosburgh Irwin, Frederick M. Johnson, George MacDonald, Winchester Noyes, John Reid, Jr., Franklin Simon, Richard A. Strong, Charles Seymour Whitman, and J. Edwards Wyckoff.

would, or under what circumstances, institute bad moral character and unprofessional and dishonorable conduct, and we do not think the Legislature intended to do so."

Claimed Fracture of Hip as Result of Fall from Hospital Bed

A boy about 13 years of age was operated on at the X. Hospital. The operation was one for osteomyelitis. Following his operation he stayed at the hospital for approximately 22 weeks. Thereafter he was discharged against the advice of Dr. A. and other physicians, but at his parents' insistence he left the hospital. He then spent considerable time in four other hospitals.

It was claimed that a day or two following the original operation the boy fell out of bed in attempting to call the nurse who did not answer the bell.

Some time thereafter a suit was commenced against the hospital and the charge was made that due to the careless and negligent treatment of the nurses and doctors, the boy fell out of bed and sustained a fracture of the left hip.

Upon the trial it was definitely proved by the x-ray pictures taken at the X. Hospital, and by a long series of x-ray pictures (some 25 in number) taken at the other four hospitals, and by means of expert testimony in interpreting said x-ray pictures that the child never had a fracture of the left hip, and it was definitely proved that the osteomyelitis had spread to the hip joint from the original site, namely, the knee.

After all the testimony was presented by both sides the trial judge directed a verdict in favor of the defendant thereby exonerating the doctors and the hospital.

Claimed Failure to Remove Rubber Drain

A girl about 17 or 18 years of age came to Dr. A.'s office complaining about a large swelling on the left side of her neck which she claimed had bothered her for approximately three and one-half weeks. She stated that previously she had been treated by Dr. B. and that he had opened the swelling and drained it. Dr. A. made a diagnosis of cervical adenitis with possible quinsy. He dressed the wound and told her to come back in a few days.

Some four and one-half years later a suit was brought against Dr. A. claiming

that the girl had been treated at his office approximately forty or fifty times, and during the course of treatment he had placed in the wound a rubber drain, and that he permitted the said rubber drain to remain in the wound for a period of some two months, and that he discharged the patient leaving the rubber drain in the wound.

Upon the trial of the action, Dr. A. denied that he had ever operated upon this girl and that according to his records and his recollection he never saw her more than two or three times, and at no time had he inserted a rubber drain. After the girl testified that she had gone to Dr. A.'s office some forty or fifty times, she was asked to identify Dr. A., and although Dr. A. sat some five or six feet from her in plain view, she was unable to do so. This was an important fact in the final decision of the case.

After hearing all the testimony the Judge directed a verdict in favor of the doctor thereby clearing him of any charge of malpractice.

Treatment of Obstructed Tear Duct

A middle-aged woman consulted a physician who specializes in eye, ear, nose, and throat work, with complaints of persistent watering of the left eye. The doctor examined the patient and found that the left tear duct was blocked. He attempted irrigation with a lachrymal syringe, but found that the fluid did not go through to the nose. He undertook to restore the function of the tear duct on two occasions by washing with a lachrymal syringe containing a solution of alkalol, but the condition of the tear duct remained unimproved. The doctor then determined to use more radical measures. He dilated the tear duct with a punctum dilator, after having anointed the instruments with an anesthetic ointment. He then passed a probe into the dilated tear duct and down into the nose under the lower turbinate. Two days later he again irrigated the duct with a solution of alkalol and found that the solution came through into the nose, proving that the passage was open. A few days later the patient returned to him, complaining of a persistent swelling under the left eye, which had developed after his last treatment.

The examination showed that a swelling had appeared under the left eye just outside the tear canal, which was moderately

hard. He ascribed the condition to cellulitis, due to the fluid having forced through the lining of the tear canal or having followed a false passage. The patient was advised to apply hot applications to the swelling. The condition, however, did not improve, and when the doctor last saw the patient professionally the swelling remained under the patient's left eye.

A malpractice action was thereafter instituted against the doctor, charging him with having been negligent in his treatment of the patient's tear duct, so as to cause the swelling beneath the eye. The case came on for trial before a judge and jury and plaintiff failed to show by any competent medical testimony that the doctor had been in any way negligent in treating the plaintiff.

At the conclusion of the testimony put in on behalf of the plaintiff the defendant's motion to dismiss the complaint was granted and judgment was entered in favor of the doctor.

Claimed Negligent Appendectomy

A girl about sixteen years of age was brought to a physician who had for many years specialized in surgery, with complaints of abdominal pains which had been increasing in frequency and extent for six weeks. The doctor made a manual examination of her by palpating the region of her appendix, and made a diagnosis of chronic appendicitis, for which he advised an operation. Two days later the doctor undertook to operate upon her under a general anesthesia. He made a McBurney incision through the skin separating the rectus muscle and opening the perineum. He found that the patient had a retrocecal appendix which could not be reached through the original incision. It was there-

fore necessary for him to enlarge the original incision, which he did, making a transverse incision of the rectus muscle. The appendix was then visible and was removed. The wound was closed in the usual manner and the patient was seen daily by the doctor at the hospital until her discharge.

A short time subsequently she returned to the doctor's office and he found that her wound had healed satisfactorily, but she complained about abdominal pains. The doctor was unable to find any reasons for said pains and concluded that she had eaten something that had upset her digestive organs, and advised her to that effect. The patient was later fluoroscoped and no abnormality of any kind was found.

Sometime later a malpractice action was instituted against the surgeon, in which the claim was made that the operation was improperly performed by him and that as a result she had sustained loss of flesh and had become anemic and that she had suffered headaches and a general run-down condition. She also attempted to charge him with causing her to suffer from pains of an ovarian character.

The case came on for trial before a judge and a jury and upon the trial the plaintiff attempted to say first, that the operation was unnecessary and second, that the doctor had unnecessarily extended the incision during the operation. The defendant, of course, testified that the operation itself was necessary and that because of conditions over which he had no control he found after starting the operation that it was necessary to cut the right rectus muscle for the purpose of extending the incision.

The issues in the case were submitted to the jury and they returned a verdict in favor of the defendant, thereby exonerating him of the charges of malpractice.

STERILIZATION GONE MAD

Medical writers in this country are amazed at the lengths to which sterilization is being carried in Germany. It seems that the authorities are now concentrating on deafness, and all deaf persons have been ordered to report for investigation.

That the hereditary health courts are taking no chances on errors of omission, is evidenced by figures that are now available. In Düsseldorf sterilization has been decided on in 200 out of 240 cases studied, in Hamburg in 761 out of 769. Other cities are proceeding at a like rate.

In the face of such unprecedented happenings, it is not to be wondered at that the medical profession in America is fighting the effort to bring medical practice under political control. How far can any guarantee of professional privacy go

under state medicine when records and reports are made the property of a lay bureaucracy?

The argument that such things could not happen in the United States cannot be accepted as final. When compulsory health insurance was introduced in Germany its bitterest opponents did not imagine that it would ever be turned to the purpose it now serves.

The only way to maintain the essential personal relationship between doctor and patient is to retain private practice. The only way to keep politics out of medicine is to keep medicine out of reach of politics. Compulsory health insurance subordinates healing to bureaucracy and places physicians and sick alike at the mercy of politicians.

BOOKS RECEIVED

[Acknowledgment of all books received will be made in this column and this will be deemed by us a full equivalent to those sending them. A selection from this column will be made for review, as dictated by their merits, or in the interests of our readers.]

Diseases Peculiar to Civilized Man—Clinical Management and Surgical Treatment. By George Crile, M D Octavo, of 427 pages, illustrated New York, The Macmillan Company, 1934 Cloth, \$5 00

Mental Deficiency Nursing—By O P Napier Pearle 16mo of 281 pages Baltimore, William Wood & Company, 1934 Cloth \$2 00

Vital Cardiology—A New Outlook on the Prevention of Heart Failure By Bruce Williamson M D Octavo of 344 pages Baltimore, William Wood & Company, 1934 Cloth, \$5 00

Essays on Chronic and Familial Syphilis.—By Griffith Evans Octavo of 91 pages illustrated Baltimore, William Wood & Company, 1934 Cloth, \$3 00

Parasitism and Disease.—By Theobald Smith Octavo of 196 pages Princeton N J, Princeton University Press 1934 Cloth, \$2 00

Applied Physiology.—By Samson Wright M D Fifth Edition Octavo of 604 pages illustrated New York Oxford University Press 1934 Cloth, \$5 50

A Textbook of the Practice of Medicine.—By Various Authors Edited by Frederick W Price, M D Fourth Edition Octavo of 1995 pages New York, Oxford University Press, 1933 Cloth, \$11 50

Surgery of a General Practice.—By Arthur E Hertzler, M D and Victor E Chesky, M D Octavo of 662 pages, illustrated St Louis, C. V Mosby Company, 1934 Cloth, \$10 00

Spinal Anesthesia—Technic and Clinical Application By George R Velez, M D Octavo of 269 pages illustrated St Louis, C. V Mosby Company, 1934 Cloth, \$5 50

Tuberculosis in the Child and the Adult.—By Francis M Poettenger, M D Octavo of 611 pages illustrated St Louis, C V Mosby Company 1934 Cloth \$8 50

Industrial Toxicology.—By Alice Hamilton M D 16mo of 352 pages With subject index New York Harper & Brothers, 1934 Cloth, \$3 00

Midwifery for Nurses.—By Henry R Andrews M D and Victor Lack M B Seventh Edition 12mo of 268 pages illustrated Baltimore, William Wood & Company, 1934 Cloth \$2 50

Nephritis and Allied Diseases.—The Pathogeny and Treatment By Robert Platt, M D Octavo of 166 pages New York Oxford University Press 1934

Manual of the Diseases of the Eye.—For Students and General Practitioners By Charles H My, M D Fourteenth Edition Octavo of 496 pages illustrated Baltimore, William Wood & Company, 1934 Cloth, \$4 00

That Heart of Yours.—By S Calvin Smith M D Octavo of 212 pages illustrated Philadelphia, J B Lippincott Company 1934 Cloth \$2 00

A Primer for Diabetic Patients.—By Russell M Wilder, M D Fifth Edition 12mo of 172 pages illustrated Philadelphia, W B Saunders Company, 1934 Cloth \$1 75

The Surgical Clinics of North America.—Vol 14 No 3, June 1934 (Mayo Clinic Number) Published every other month by the W B Saunders Company, Philadelphia and London Per Clinic Year (6 issues) Cloth \$16 00 Paper \$12 50

A Short History of Some Common Diseases.—By Divers Authors Edited by W R Belt Octavo of 211 pages New York and London, Oxford University Press 1934 Cloth \$3 50

A Compend of Diseases of the Skin.—By Jay F Schamberg, M D and Carroll S Wright M D Ninth Edition 12mo of 331 pages, illustrated Philadelphia, P Blakiston's Son & Co [c 1934] Cloth \$2 00

The Spastic Child.—By Marguerite K Fischel 12mo of 97 pages illustrated St Louis C V Mosby Company 1934 Cloth \$1 50

The Laboratory Notebook Method in Teaching Physician Diagnosis and Clinical History Recording.—By Logan Clendinning M D Octavo of 71 pages St Louis C V Mosby Company, 1934 Paper, 50c.

BOOKS REVIEWED

Practical Methods in Biochemistry.—By Frederick C Koch Octavo of 282 pages illustrated Baltimore, William Wood & Company, 1934 Cloth \$2 25

The author presents a manual of biochemistry which is primarily intended as a practical companion to Matthews' textbook. However he has incorporated a matter in order to with the practical with the chemistry of digestion and urine. The principal analysis are based on a very valuable preparation of all instructions for use of colorimeters.

W S COLLENS

Hypertension and Nephritis.—By Arthur M Fishberg M D Third Edition Octavo of 668 pages illustrated Philadelphia Lea & Febiger, 1934 Cloth \$6 50

The appearance of the first edition of this work impressed everyone with the thoroughness, accuracy, and care of the presentation of this difficult subject.

One cannot realize the completeness of this study without several careful reviews of the volume. Every phase of kidney dysfunction has been considered in a scholarly manner. The book is a masterpiece and its necessity for a third edition in a short time proves its value.

No one who wishes to know of kidney disease and allied conditions can afford to miss this new edition which brings to date recent progress in the care of nephritic conditions and which includes obscure states not mentioned in the previous editions.

HERVEY M MOSES

Aids to Qualitative Inorganic Analysis.—By R. G Austin 16mo of 204 pages Baltimore William Wood & Company, 1933 Cloth, \$1 50

This little book has been written to assist medical students in the analysis of simple inorganic substances. The chemical reactions are clearly defined. And their

study will give the student a good knowledge of chemistry in general. The text is well arranged and makes for easy reading. At the end of the book a number of inorganic substances of importance in medicine and pharmacy have been placed.

EDWARD H NIDISH

Recent Advances in Psychiatry.—By Henry Devine M D Second Edition Octavo of 364 pages Philadelphia P Blakiston's Son & Co. 1933 Cloth, \$4 00

The author has revised his classic first edition there by making it more true to the title although there is included much material that can scarcely be called recent advances. These inclusions, however enable the volume to be compared somewhat to an advanced textbook without rudimentary material. It is less a critical survey of recent literature and is more of a discursive book for graduate and advanced work.

Three new chapters recent developments in material in general has style of presentation recommends itself not alone to graduates and advanced workers, but to sufficiently interested students and general practitioners.

IRVING M DERRY

New and Nonofficial Remedies, 1934, containing descriptions of the articles which stood accepted by the Council on Pharmacy and Chemistry of the American Medical Association on Jan 1, 1934 12mo of 510 pages. Chicago, American Medical Association [c. 1934] Cloth, \$1 50

New and Nonofficial Remedies 1934, has the same pleasing format and helpful mechanism that has characterized it in past years. The enrichment of the index even started a few years ago is continued and its value even increased by some desirable simplification of cross references.

The Council has made the usual careful revision of the book. The general article Lactic Acid Producing Organisms and Preparations has been practically rewritten. The articles on arsenic preparations, chinoinon,

vioform, ethylhydrocupreine (with deletion of references to optochin base), typhoid vaccine, and others have been revised thoroughly. Comparison with last year's volume will show that revisions of more or less importance occur in many other chapters.

Among the preparations newly included in this volume are: aminophylline, neo-iopax, benzadrine, serums containing type II pneumococcus antibodies, autolyzed liver concentrate and extralin, metycaine, and sodium morrhuate.

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association for 1933. 12mo. of 188 pages. Chicago, American Medical Association, 1933. Cloth, \$1.00.

The main bulk of the volume, which is, incidentally, considerably increased over that of recent annual volumes, is taken up with reports on products which the Council has found unacceptable for inclusion in New and Nonofficial Remedies.

Die intrakutane Kaninchenmethode zur Auswertung von Diphtherie-Toxin und Antitoxin.—By Claus Jensen. Octavo of 211 pages, illustrated. Copenhagen, Levin & Munksgaard, 1933. (Acta Pathologica et Microbiologica Scandinavica, Supplement XIV.)

The author describes the use of rabbits in the determination of the diphtheria toxin and antitoxin as an aid or replacement of the Ehrlich method. The different methods of standardization of the units of toxin and antitoxin and their practical application are fully described. The work is divided into two parts. The first part deals with the history of the technic and the various units used by different workers. The second part deals with the intracutaneous rabbit method and describes the clinical appearance and histology of the intracutaneous reaction of the diphtheria toxin, as well as the effect of temperature, dilution, and individual variations in the use of toxin and antitoxin. There is also a detailed description of the practical application of the method.

EDWARD H. NIDISH

La Lutte Internationale Contre le Cancer.—By Dr. Jacques Bandaline. Octavo of 947 pages, illustrated. Paris, Norbert Maloine, 1933. Paper Fr. 135.

As the title indicates, this book is a very detailed survey of the facilities, clinical and experimental as well as social, comprised in every country in the world in the anti-cancer campaign. Furthermore an account is given of the inception and history of the fight against, and the study of, the cancer problem, so that in fact the volume is a veritable encyclopedia of information regarding the world's resources engaged in this problem. The appendix contains a complete list of special hospitals, or wards of general hospitals or clinical departments of experimental institutes devoted to the study and treatment of cancer throughout the world, including such information as personnel, number of beds, amount of radium on hand, strength of x-ray apparatus, etc.—a reference work extremely useful for consultation.

PHILIP FRANK

Aids to Neurology.—By E. A. Blake Pritchard, M.D. 16mo. of 376 pages, illustrated. Baltimore, William Wood & Company, 1934. Cloth, \$2.00.

This vest-pocket edition is an attempt to summarize the clinical conditions that most commonly result from diseases of the nervous system. It is intended for the use of the junior medical students. Separate chapters are devoted to symptomatology, the peripheral nervous system, spinal cord, brain, and the sympathetic nervous system.

It is quite a good book and one that will find favor with the busy medical student. The author has not intended it to be more than an aid to the study of neurology, and it therefore can serve only as a supplement to the more complete textbooks on neurology. When properly used, the book will serve a good purpose, and is therefore recommended, as its title implies, as an aid to neurology.

IRVING J. SANDS

Das Wunder der Heilung durch Eigenes Blut.—By Dr. Ludwig Sternheim. Octavo of 64 pages. Bern, Switzerland, Hans Huber [c. 1933]. Paper, Fr. 3.50.

In this pamphlet the author discusses the healing powers of one's own blood. He describes the condition of the tissues in health and disease, cell irritability, and the defense mechanism against harmful influences. He also discusses the artificial stimulation of immunity in subacute and chronic diseases, and the use of one's own blood for such purposes. The technic of this use of blood is described very clearly, and the various diseases that were benefited by its use are enumerated.

EDWARD H. NIDISH

Practical Medicine Series.—Comprising Ten Volumes on the Year's Progress in Medicine and Surgery. Series 1933, Chicago. The 1933 Year Book of Neurology and Psychiatry. Neurology, edited by Peter Basso, M.D. Psychiatry, edited by Franklin G. Ebaugh, M.D. 12mo. of 470 pages, illustrated. Cloth, \$2.25.

This is the yearly volume welcomed as a critical survey relating to the fields of neurology and psychiatry. The same editors continue with their expertly selected material, consecutively arranged and not too briefly elaborated. Editorial comments distributed throughout the arrangement are constructive and clear.

The quoted statement that the volume and quality of neurological literature has not been affected by the depression applies to the psychiatric division as well. The volume is produced for practitioners familiar with physical and mental disease and is an excellent summary of references for those wishing the later views in neurology and psychiatry.

IRVING M. DERBY

Metabolic Diseases and Their Treatment.—By Dr. Erich Grafe. Octavo of 551 pages, illus. Phila., Lea & Febiger, 1933. Cloth, \$6.50.

A detailed discussion is not possible in a brief review. In general, the author's viewpoint is in accord with that usual in this country. However, there are many matters of detail in which this is not the case, and his views are clearly and forcibly expressed. This adds special interest for the informed and careful reader. The material is clearly and thoughtfully presented. The translation is in fluent and idiomatic English. Errors are few.

It is a real pleasure to the reviewer to recommend a volume such as this.

CARL H. GREENE

Applied Pharmacology.—By A. J. Clark, M.D. Fifth Edition. Octavo of 632 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., 1933. Cloth, \$5.00.

In the preface to the first edition of this textbook, the author stated that he had endeavored to give an account of the direct scientific evidence for the therapeutic action of the more important drugs, and to demonstrate the importance of this knowledge in the clinical application of drugs. This is an ideal goal, but the field covered is so broad, that much relevant detail has of necessity been sacrificed, in order to keep the presentation between the covers of a single volume. As such, it will not supplant the present standard treatises on either pharmacology or therapeutics.

The material is interestingly and readably presented. The discussion of individual disease syndromes is one of the reasons for the popularity of the book. The appearance of this, the fifth edition, is a measure of the latter.

CARL H. GREENE

The Great Enigma.—A New View on the Outlook of Life. By Hugo H. Schauinsland, Ph.D. Translated from the German by Walter H. Schauinsland, Ph.D. 12 mo. of 90 pages. New York, E. P. Dutton & Company, 1933. Cloth, \$1.25.

In this little book the author aims to show that we are still very much in the dark regarding ourselves, in spite of wonderful scientific achievements. He reflects in a philosophical vein on the communal habits and instincts of lower animals, and minimizes man's attempts to supplant Mother Nature with flimsy laws and principles.

The physician reader will hardly sympathize with such a helpless attitude. We physicians are realists, and it is contrary to medical thought to be powerless in the face of uncontrollable bodily destruction. A remedy, however useless it be, is better than none.

This book is a simple confession of Man's helplessness on this earth, and yet is far more penetrating than many of the so-called enlightening technical treatises on scientific progress.

EMANUEL KRIMSKY

A Handbook of Psychiatry.—By John H. Ewert. 12mo. of 267 pages. Baltimore, William Wood & Company, 1934. Cloth, \$4.75.

This is an attempt to present in synoptical form the accepted tenets of modern psychiatry. It is made up of well-outlined, highly condensed material. As such it should make a rapid reference work, ideal for the student preparing for his examinations or the lecturer, hastily reviewing his material.

It is divided into six sections, consisting of an introduction, psychoses, psychoneuroses, mental deficiency, legal relations of mental disorder, and an appendix.

The prospective reader will find it to be very complete, virtually every phase of modern psychiatry has been ably epitomized.

HAROLD R. MERWARTH

NEUROLOGICAL ASPECTS AND TREATMENT OF BIRTH INJURIES

FARL R. CARLSON, M.D.

Director, Department of Education of the Birth Injured, Neurological Institute New York City

The birth injury group embraces a wide variety of conditions. Such conditions are frequently referred to as spastic paralysis. This is an unfortunate misnomer, since an intracranial birth injury can give rise to almost any kind of neurological syndrome. There may be spasticity as well as flaccidity, hypotonic as well as hypertonic muscles, ataxic as well as athetoid states, all depending upon the location and the extent of the injury.

If the injury involves trophic centers in the brain, there will be corresponding changes in the muscle contour. Just because a muscle group is small, it does not necessarily follow that we are dealing with an atrophy of disuse. The most active muscle groups will remain small, in spite of activity, if the lesion involves trophic centers which limit the nutrition to the muscle. On the other hand, if the trophic changes are such as to cause an excessive nutrition, the reverse will hold true in spite of limited muscular activity.

The essential factor to be determined in training these cases is whether the disease is progressive and whether any degree of mentality is present. Evidence that the disease is progressive places it beyond the reach of effective training.

Since cases of encephalitis and the hereditodegenerative types of diseases, which are not amenable to training, can also simulate the clinical picture arising from intracranial trauma, it is obvious that, if these progressive factors be not carefully

sive ty training, the outlook for the treatment of the birth injured is far from encouraging. Developmental defects have often been wrongly diagnosed as birth injuries and in many instances, it is impossible to make the distinction. In several cases we have

seen, the patients have not only shown a history of having been born cyanosed and asphyxiated and with the aid of forceps, but, in addition, the presence of branchial clefts, cleft palate, and other stigmata of degeneration have made it strongly suggestive that a developmental defect might predispose to a birth injury. In this connection, the case of identical twins should be mentioned, in whom the encephalogram revealed identical lesions. There was also a history of dystocia. Had only one twin survived, the conclusion would have been that the condition resulted from trauma, but the evidence of identical lesions, which were mirror images of each other, made any other cause than failure of development highly improbable. However, in the blastophoric anomalies we have seen, the intelligence has suffered far beyond the stage which will respond to treatment.

When it comes to evaluating the mental resources of these patients, we find an equally wide range of differences. An intracranial birth injury can give rise to such extremes as idiocy, on the one hand, with little or no muscular difficulties, to cases of purely motor handicaps, on the other hand, with little or no mental disturbances. We must therefore be very careful before giving any appraisal of the latent mental capacities of the birth injured. The grimaces and drooling frequently seen in these patients have not infrequently led to their being mistaken for idiots or considered feeble minded, whereas such a condition should no more be a criterion of mental deficiency than is a disturbance limited to a leg or foot muscle. The mentality is therefore often extremely difficult to evaluate, especially where the physical affliction is severe and far out of proportion to the intellectual ability.

We cannot rely too much on intelligence

tests, since the majority of them require the use of muscles, over which the patient may have little or no control during the test. As an arbitrary standard, however, such tests are useful in serving as a starting point. If subsequent tests after a period of training reveal higher rating, we know that the patient is making progress.

Aside from the purely physical affliction of the muscular system, we must take into consideration the possibility of special disabilities such as speech, reading, hearing and spelling. We have found that almost 15 per cent of our cases have definite impairment of hearing, sufficiently severe to interfere with their schooling. In many such cases, the mother denies that the child has any trouble in this respect, whereas, carefully worked out otographic tests will reveal an appreciable loss in hearing. Obviously, if the child is deaf to certain tones, speech is going to suffer.

The question of handedness must be particularly investigated before outlining any educational régime. "Writing," according to Dr. Orton, "like other fractions of the language faculty, is intimately related to the problem of unilateral cerebral dominance, since it is frequently lost in the adult as a result of destructive lesions of the dominant hemisphere and is not disturbed by lesions of comparable extent and locus in the subjugate hemisphere." According to him, "failure to acquire the usual cerebral pattern of the adult, *i.e.*, unilateral dominance, lies at the bottom of the selective retardation in learning to read, occurring in children who are otherwise able."

The frequency with which we are confronted with these special disabilities has resulted in our insisting upon a complete analysis of each patient before he is allowed to continue with his schooling. Then, if any special handicap is discovered, an educational program in accordance is outlined. Instead of having a child, for instance, with a reading disability forced to carry the usual routine curriculum, special instructions are given. The child with the hearing defect must be handled quite differently. The simplest solution is the establishment of special schools for which the proper individuals can be carefully selected, only after complete examination and then a program outlined whereby both physical and intellectual development can be simultaneously controlled.

The behavior of the birth injured must be thoroughly investi-

gated before attempting any treatment. If the lesion involves thalamic centers, where we get conditions of forced laughing and crying, such a situation is going to be more difficult to handle than one that is primarily of psychogenic origin. So far we have had very little success in coping with the disturbances due to extensive thalamic lesions. The psychogenic problems, however, can often be handled in much the same way as the child who, though physically and mentally normal, has become a behavior problem.

From what has been said it is evident that the possibilities or limitations of the birth injured cannot be determined by merely testing the reflexes of the muscles, as is so frequently done. The thought processes, it must not be forgotten, are also reflex activities and these may be as hyperactive as the knee jerks. It is, therefore, just as important to control the reflexes which are running riot in the thought processes as it is to control the reflexes of the muscles. Merely a set of exercises is, therefore, of no avail unless they are conducted in conjunction with an academic program.

Unless there has been a gross insult to the cortical cells, when idiocy, without apparent motor disturbance, may occur, the birth injured can be considered essentially as a hyperkinetic type of individual. Since the injury is generally a diffuse one, we seldom find a pure type of disturbance such as we see in the case of a tumor, but rather combinations of athetosis with recurrent spasticity or a striocerebellar type of disorder. Regardless of the type of movement which predominates, there is usually a tremendous amount of overflow of nerve energy on attempted voluntary movement. In the same individual the reactions to this overflow on some occasions may not be apparent, or they may be limited to only one or two muscle groups, while, at other times, the entire body musculature is involved.

We must not forget that, in the normal new-born infant, the movements are also incoordinated and appear to result from irradiation of impulses throughout the body. Studies in normal child development show that these undifferentiated responses are readily adaptive to environmental conditions. These studies have proved most valuable in assisting us to help the infant in forming desirable associations and becoming better adapted to his continually changing environment.

Why should not similar studies be made on the birth injured? Granted that the progress of the normal child is more spontaneous and that no steps need be taken to teach it to sit or stand, the irritability of nervous tissue is nevertheless a relative thing and the proper type of conditioning is just as important in one case as in another. Granted also that the range of differences in the behavior of the birth injured is greater than with the normal, progress in both instances depends upon the fate of the overflow of nerve energy.

The problem, then, is to find adequate channels of expression for the excessive energy which interferes with the birth injured's activities. Since man is an energy producing machine, it is important, not only to relieve the tension of the birth injured's muscles through proper relaxing exercises, but, after the tension has been relieved it is essential to redirect that energy into other channels, especially along academic lines, in order that the patient may become more objective in his thinking.

At the Neurological Institute, the birth injured cases, after having been thoroughly investigated, are placed in a special school where mental and muscle training begin and proceed simultaneously, with a minimum amount of distraction from a definite daily routine.

One hour daily is allotted to muscle training, followed by a period of rest and during the remainder of the waking day, the patients are kept occupied by studies and such games as tend toward enhancing muscular expression, as well as to make the patient objective in his thinking. Care is exercised in the selection of patients, cases of marked mental deterioration and those showing progressive disturbances are excluded. A close contact with the home is kept to make certain that the parents are cooperating in the program which, in the main, tends to make the child self-attendant. This is necessary to augment, rather than to distract from the influences of this school. Emphasis is placed on the fact that, when the child is ready, he should be transferred to a normal school environment.

With respect to the specific types of exercises, it is very difficult to lay down any set rules, since these exercises must be adapted to each individual case. The primary aim of the exercises is to teach the patients to make an active movement with the minimum amount of muscular effort. At the outset, it must be remem-

bered that we are working with patients who have never been able to perform a normal coordinated movement. This is different from the situation of the patient who is born with normal faculties and later in life sustains a paralysis. With the latter, training is a matter of reeducation. In the case of the birth injured, however, training is not reeducation but an endeavor to initiate a pattern for normal coordinated movement out of a pattern complex of massive muscular responses which have never been differentiated. If the patient is an infant, these mass action patterns can be differentiated into segmental movements by passively moving the infant's arm to the rhythm of a lullaby. In time, the infant will learn to associate the action of moving the arm with the singing of the lullaby so that, when the song is heard subsequently by the infant, he will actively move his arm. After a pattern for segmental muscular activity has once been established, further differentiation becomes less difficult. In other words, the baby who responds by extending all four extremities simultaneously, when a toy is presented to him must be taught to use only the muscles necessary for the act of stretching out the hand and no others.

In the case of older children training is also directed toward breaking up mass action patterns and this becomes easier as the child learns to cooperate. Such factors as anxiety, fear, and self-consciousness augment the adventitious movements and, therefore, it is important to eliminate the emotional element from the muscular act as much as possible. This is especially true when the patient presents much atetosis. In such cases, instead of having the patient concentrate on the exercises themselves, the patient's attention should be focused on something irrelevant to the situation when doing the exercises. Slow, rhythmic music will often obviate this difficulty, or anything which will tend to reduce the sensorial input to a minimum will be helpful.

In cerebellar disorders, where we rely a great deal on the optic pathways in training, it is important to correlate the visual acuity with the muscular act. The ability to walk in such cases is often facilitated if the patient will look where he walks. Focusing on an object toward which he is going is helpful in maintaining the head erect, which is likewise important in correcting any vestibular difficulties. In this connection, it should be emphasized that

the ability to walk and maintain balance will be greatly assisted through the correction of visual difficulties such as a strabismus, either by surgery or by the use of lenses.

A calm and quiet atmosphere is essential for encouraging relaxation. The physical trainer should be a person with a temperament and personality that is conducive to relaxation. Before the actual exercises are begun, there should be an initial period of relaxation lasting for about five minutes. The active exercises should be carried out with the least possible amount of overflow, that is, with just as little effort as it takes to produce a free and easy movement. It should commence with slow, coordinated, rhythmic forms of exercise, beginning with the big groups of muscles, such as the proximal joints, the shoulder and the hip, with the aim of gradually working in the knee and elbow and finally the hands and feet. Sometimes it is necessary, with small children to passively assist them with these exercises, until they are able to perform them themselves.

The control of the big body muscles should be acquired first and then the smaller groups, etc. Placement exercises such as walking on lines, putting fingers on dots, and placing pictures on blackboards is helpful after the control of the larger muscle groups has been established. Walking before the mirror is also an aid. If passive stretching of a muscle group is necessary, it should only be done when the antagonistic groups have become relaxed. Treatment in water, while it is conducive to relaxation, because of the elimination of the force of gravity, is, nevertheless, not as effective as in the treatment of poliomyelitis conditions. It seems that, in the case of the birth injured, the ability to relax does not carry over as well in water treatments as when the exercises are given on the table.

It is better to let the birth injured child practice the thing that he is to learn, making the erroneous or unessential movements in first attempts and later eliminating them, than to restrict his activity to simpler movements in the process, with the expectation that the ability so gained will immediately carry over into the more complicated coordination. In other words, it would be like putting the cart before the horse, if we attempted to teach a child to play the piano or to learn to write, if the grosser groups of muscles necessary to control the hand had not been treated first. The point of not complicating the per-

formance asked of the birth injured, by setting up too many sensory stimuli to which he must attend simultaneously, is of great importance. A little guidance toward relaxation before attention is focused on the more complicated acts is an efficient method of training.

Surgical procedures such as the Hunter and Royal operation on the sympathetic nervous system have been of little value, according to the consensus of opinion. Muscle transplants, nerve sutures, tenotomies, and alcoholic nerve injections, should be resorted to only after a thorough trial has been given in muscle training. Such procedures aid in muscle training but should not be undertaken unless they can be followed by a thorough program of corrective exercises.

With respect to medical treatment such as sedatives like luminal, bromides, etc., these are not to be advocated except in severe cases and preferably limited to those with convulsive seizures. A preparation of luminal, thyroid, and calcium is sometimes valuable in combating convulsions. In such cases an encephalogram should be made to reveal defects which might be treated surgically. Alcoholic beverages, while they are exceedingly valuable in temporarily eliminating the adventitious movements during their effect, should not be resorted to because of their habit-forming tendency. Any substance which tends to depress the mental activity makes the patient less responsive to an educational program which is so important in obtaining results. A cup of coffee will often make the patient more responsive to his studies and exercises than will a sedative. Glycine has been beneficial in many of our cases.

Speech training should be attempted only after a thorough analysis of the speech situation has been made. If the encephalogram reveals an injury involving the operculum surrounding Broca's speech area, we cannot hope to help the difficulty. If audiometer tests reveal a deficiency of hearing, exercises to increase the acuity of that faculty must be prescribed. Tests should also be made to determine the handedness of the individual so as to encourage the use of the hand that is most likely to establish a unilateral cerebral dominance. The latter is often aided by combining the spoken word and writing simultaneously, preferably with the use of blackboard so as to enable the patient to write in large words as he attempts to speak the word which he is writing. The movements of the hand

will also take care of some of the excessive overflow of nervous energy which interferes with speech. Tongue placement exercises in front of mirrors are also useful. Speech, however, is a very intricate muscular process and, since, in the case of the birth injured, its disturbance is intimately tied up with the general condition, we cannot hope for much improvement in this respect until the patient has learned to control the larger groups of muscles or has acquired a general improvement.

SUMMARY

The birth injury group embraces a wide variety of conditions and, although among them are the more serious idiotic cases in which prognosis is hopeless and for which there is no effective treatment, we also have a large number of cases laboring under purely motor handicaps, with little or no mental disturbance and in which there is a possibility of obtaining extremely good results if proper treatment is instituted at an early age. The essential factor to be determined is whether the disease is progressive and whether any degree of mentality is present. Evidence that the disease is progressive places the case beyond the reach of effective training; a profound degree of mental defectiveness excludes the case because there is no undamaged residue with which to work. Care must be exercised in differentiating between a special disability and a deficiency. The latter is not amenable to treatment, whereas a special disability, such as in speech and in reading, can often be greatly benefited under proper guidance.

Deprived of early training, the patient is not only delayed in speech, locomotion, and performance of skilled acts in general, but the longer the delay, the slower will be the progress, because of the faulty motion habits to be unlearned. In the normal, as well as with the birth injured, the capacity for skilled and accurate muscular efforts depends upon his memory of them and upon his power of recalling them and evoking them again. Just as writing, speaking, and certain gestures are conventional modalities of expression, gained through the proper training of the normal individual, so the muscular movements of the birth injured come to represent unconventional modalities of expression, unless proper conditioning is instituted when the child's associative system is largely unformed. The purpose of this paper is, therefore, to emphasize that the problem of the birth injured is not merely an orthopedic one, it is an educa-

tional problem in itself which, for its solution, demands the closest cooperation between physician, teacher, and parent.

187 FT WASHINGTON AVE.

ABSTRACT OF DISCUSSION

DR. WALTER O. KLINGMAN. For the past two and a half years it has been my privilege and pleasure to have been associated with Dr. Carlson as Medical Advisor to the Department for the Re-education of the Birth Injured at the Neurological Institute of New York. During that time we have seen hundreds of children suffering from various types of paralysis, most of which were palsies in consequence of birth injuries and many of them not. From this large group of infantile palsies we endeavored to select those which we felt reasonably certain resulted from birth injury although in many instances this is difficult to establish absolutely. This selected group of cases was then used for treatment and study and excludes such cases as are caused by known developmental defects, aphasia and ageneses, amaurotic family idiocy, encephalitis, syphilis, etc.

In studying the material we have been impressed with certain features which we wish to call to your attention. When one speaks or hears of birth injuries one immediately thinks of, or visualizes, the classical clinical picture of Little's disease or spastic paraplegia, largely, probably, because Little was one of the earliest to associate the condition with birth injury. Our experience has been that the clear cut, purely paraplegic cases were not the common or usual type encountered but that the clinical picture was of a greatly varied type. Fortunately we have been able to obtain a certain amount of pathological material from the Sloan Hospital Babies Hospital, and Neurological Institute, to demonstrate the varied lesions that are encountered in birth injuries. Except for the brains of infants that die immediately after or at birth, material for study is extremely difficult to obtain so that our study is not as complete as we wish to have it and expect to have it. If one recalls briefly the various nerve centers and tracts involved in the successful production of movement it is easy to understand why we find such varying pictures with all degrees of spasticity, ataxia, athetosis, choreic features, evidence of thalamic involvement anterior horn cell damage hypothalamic and trophic disorders.

When one considers these injuries and the clinical conditions that cause them one thinks at once of difficult and forced labors. It is quite needless here to mention the various difficulties and conditions contributing to forced or difficult labor but there are certain obstetrical conditions deserving of mention aside from prolonged difficult labor and instrumental delivery. Version and breech delivery, as Crothers pointed out is unphysiological and dangerous because of traction and a most dangerous procedure from the standpoint of the central nervous system. Forty five per cent of the cases which we have studied gave a history of instrumental delivery and in 41 per cent there was definite evidence of trauma at the time of delivery. Brachial plexus and spinal cord injuries in most cases are obviously due to technical difficulties encountered in breech deliveries or in impaction of the shoulders behind the symphysis. Aside from the difficulties encountered in labor and at delivery, another important factor to be considered is immaturity of the infant. In our study the percentage of immature infants runs between 18 and 20 per cent. The term 'imma-

ture" meaning here any infant who weighed less than 2,500 gm. at birth irrespective of the length of duration of the pregnancy. In this respect we feel that because of immaturity of the cerebrovascular and meningovascular system, the capillary and vascular bed in most instances is not sufficiently developed to withstand the trauma associated with uterine contractions and passage through the birth canal.

The early diagnosis of birth injuries is not always simple. In obtaining our histories we have been impressed with certain fairly constant features that are present. They are immaturity, increased somnolence, increased crying, asphyxia, apneic attacks, irregular breathing, failure to suckle, rigidity, opisthotonos, slow rhythmical adduction and abduction, persistent singultus, yawning, and frequent vomiting. But the outstanding symptoms are, however, convulsions and localized twitchings and difficulty in suckling; 61 per cent of the cases gave a history of difficulty in suckling and 26 per cent of the cases gave a history of convulsions or muscular twitchings.

All of the signs and symptoms just mentioned vary greatly and one finds all degrees of them present. About half of the infants do not show *other symptoms until the latter part of the first year* when convulsions and late development of the static functions are noticed and then gradually the varying pictures of spasticity, athetosis, ataxia, etc., as myelinization in the nervous system becomes complete.

Much has been written and said in explanation of the various disturbances in movement that one sees in cases of birth injury, but if we recall the underlying pathology and the many nerve centers and pathways involved, we can visualize almost any kind of clinical manifestation; this has been exactly our experience in examining hundreds of these children. One can see the complexity of the nervous mechanism which underlies the functions of posture and movement in these children and one can easily see how movement and posture may be seriously interfered with. Any lesion in this complex network of neural connections will upset movement in some way or other, and the effect of injury of the main centers and tracts of the neuron arcs on the functions of the peripheral arc, on the movement of the muscles, the posture, and the reflexes, is the purpose, of course, of our clinical examination and should precede any attempts at reëducation. Considerable speculation has been made as to how much the higher cortical centers enter into the various disturbances of motion and posture, whether the lesions are cortical or subcortical, etc. Observations on many of the children under various circumstances has shown the striking effects which such factors as concentration, fear, attention, and self-consciousness play in controlling movements and posture. We likewise have observed the effects that ether and alcohol has on them. Recently we have had occasion to observe experimentally and also clinically certain features of this, which warrant comment but also considerable more investigation. The question of localization is still far from being answered.

The severity of the lesions or the diagnosis of the condition in doubtful cases can be estimated frequently by the use of the encephalogram and if one could examine all cases ideally, one should insist upon encephalogram study in each instance especially since Dyke and Davidoff have worked out so carefully the localization of cerebral structures by the use of the encephalogram.

Aside from the purely muscular reëducation of the birth injured, treatment must be extended into more than just this field. As yet many of these other fields are still in the process of investigation by us, but such special disabilities as speech, hearing, vision, reading, writing, and intellectual training in general are presenting themselves. We have been particularly fortunate to have the help of such investigators as Chesher and Dozier, of Orton's research staff in language and other disabilities in studying these problems for us. Our feeling as a result of a good many of these studies is that about 15 per cent of the cases have a hearing disability. The majority of the speech disturbances are those of expressional speech which is a part of the general motor disability. Special disabilities in reading, writing, stuttering, and stammering are probably not any more frequent in the birth injuries than in other children, implying that they would have the disability whether they had the birth injury or not. Nevertheless from the educational standpoint we have found it of tremendous help in having the special disability analysis made in outlining the school program.

Probably one of our greatest problems, once a child has been accepted for treatment, has been that of helping the afflicted child to adjust himself to his environment and the conditions of life as he will meet them. Behavior and psychiatric problems are present in practically every case and bear tremendous importance in the success one has or does not have in the treatment. The social and environmental status requires careful study and thought. The personality make-up and inherent constitutional factors all play important rôles in these children.

In many of our older children and adolescents we have found a high percentage of actual psychotic or potential psychotic states which have been built up largely by the handicaps and inability to adjust to those handicaps.

There is another group about which a few words should be said as they require special care and treatment: the group in which there has evidently been injury to the hypothalamic region with subsequent endocrine and various types of metabolic disturbances.

To us who are interested in the birth injury problem, there are still many unsolved problems requiring further investigative work before we can express our findings about them. The muscular nutrition problems, creatinine metabolism studies, and other biochemical studies, the factors entering into spasticity, the relationship of CO₂ fluctuations to spasticity in the respiratory irregularities and numerous other problems are being studied by us now in the hopes of adding still more help in the care of the birth injured.

DR. IRVING J. SANDS: My necropsy material has enabled me to conclude that there are several places of predilection in birth injuries in the brain. The most common injury is that of a tentorial tear, and therefore the cerebellum or its peduncles are injured. The next most common site of injury is the periventricular areas. Lastly, the pons is the seat of injury. Ventricular hemorrhages do occur, but relatively infrequently. Fortunately, the frontal lobes and the anterior half of the brain in general are usually spared. Therefore the intelligence of these patients is usually good. What can be done in the line of therapy is well illustrated by the two excellent papers which Dr. Carlson and Dr. Klingman presented this morning.

THE TREATMENT OF SINUS THROMBOSIS

T L SAUNDERS MD
New York City

The scope of this paper will be confined to infections of the lateral and sigmoid sinus secondary to suppuration in the middle ear and mastoid process. The treatment of sinus thrombosis is essentially surgical. While cases of sinus thrombosis can and do get well without operation, no thinking and intelligent practitioner can conscientiously advocate any treatment that does not include some surgical procedure.

The objective of the treatment of sinus thrombosis is the removal, as far as possible, of the affected focus in the sinus and the prevention of the passage of pathogenic organisms into the general blood stream. It is the conception of the writer that the disease in the sinus is a progressive lesion that successive waves or crops of micro organisms are thrown into the blood stream. These are taken care of by the general resistance of the patient and an apparent improvement occurs until another wave is thrown into the blood stream from the original focus. If this cycle is allowed to go untreated, the resistance of the patient is overcome and a fatal issue ensues. In the cases that heal spontaneously—and these are rare—the thrombus in the sinus becomes organized and micro organisms are destroyed by the various resisting agencies that reside in the body of the individual.

Operation in sinus thrombosis can be divided into two main parts: (1) operation on the sinus itself, (2) operation on the jugular vein. While, for purposes of convenience the operation on the sinus itself is first discussed it by no means follows that in every case this procedure precedes the measures devoted to the treatment of the jugular vein.

The operation on the sinus itself has as its aim the eradication as far as possible of the original focus of infection. It may be stated at the outset that no surgeon imagines that the original focus in the sinus is completely eradicated by any operative procedure. However, it is true that the major portion is eliminated and whatever peripheral or residual infection remains is disposed of by the resisting forces of the body. It is understood that before the operation on the sinus is performed the

mastoid cavity has been everted either in the simple or radical operation. The author does not know of anyone whose practice it is to operate upon the sinus and leave the focus in the mastoid untouched. In brief, the operation on the sinus consists in removing the sinus plate within the cavity of the mastoid below as far toward the jugular bulb as is possible without endangering the nerve and posteriorly as far backward as is necessary to expose the clot within the sinus or to expose the healthy sinus wall. As a rule the torcular herophili are the posterior limit of this exposure.

It has seemed to the author that in the last few years fewer clots in the sinus have been encountered than previously. It has been his practice as a routine to expose enough sinus to make it possible to compress with iodoform plugs the posterior and inferior limits of the exposed sinus and still have enough exposed sinus between the plugs so that it can be carefully and deliberately incised and clearly demonstrated whether the posterior or the inferior end is free of clot.

In the writer's opinion, the actual method of removing the bone from over the sinus itself is of considerable interest and sometimes a matter of extreme difficulty. Premature opening of the sinus before the plate has been sufficiently removed is an unfortunate surgical accident and adds in no small measure to the difficulty of the operation. This cannot always be avoided. The author's individual preference and method for removing the bone of the sinus plate is to shave it down to a minimum thickness with a careful use of the chisel and curette and then to lift it gently from the sinus with the careful use of the latter instrument. During this procedure it is essential that any possible adhesions between the sinus and the sinus plate be separated by introducing the curette between the sinus and the bone before it is pried away. Theoretically, the rongeur is a useful instrument in this procedure but the author has torn so many sinuses while using it that he has adopted the former procedure and has reserved the rongeur for the exceptional case.

After the sinus has been uncovered to a

sufficient extent, iodoform gauze plugs are placed above and below and the intermediate area is carefully incised in its longitudinal axes taking care to enter the lumen of the sinus but not to pass through it and injure the cerebral tissue that lies to its inner side. Theoretically, this procedure should be easy. Practically, the placing of the gauze plugs so that they completely occlude the posterior and inferior lumen is a matter of some technical difficulty. After this has been accomplished successfully and the sinus excised, the plug should be lifted from the interior end. If free bleeding follows, it is good presumptive evidence that there is no clot in the inferior end or in the jugular bulb.

This being the case, the inferior end of the sinus is repacked and the plug lifted from the posterior end, and if free bleeding follows, one can assume that there is no occluding clot in the sinus. If the sinus is occluded by a firm clot, it will be readily seen upon excision, and immediately the posterior end of the sinus plate should be removed until the posterior limits of the clot have been reached. The clot should be gently lifted out with forceps or a dull curette. (In the opinion of the author curetting of the interior of the sinus is a procedure that is contra-indicated.) After this has been accomplished, the same procedure is applied to the anterior or inferior end of the sinus. If the clot is found occluding the lumen in this location, an attempt to remove it may be made by the use of a dull curette or by gentle suction applied with a suitable instrument, such as a small catheter, to the clot itself. Promiscuous curetting of the inferior end and too vigorous efforts to enter the jugular bulb through the lateral sinus are contra-indicated. It is better to remove the clot as far as possible and leave the rest to nature.

Cases of sinus thrombosis that are marked by the presence of a frank clot are those that are fairly easy to deal with and in this connection it is hardly necessary to state that the absence of the visible clot and free bleeding from either end does not exclude a thrombophlebitis that is sufficient to account for all the symptoms. There has been some controversy as to the actual position of the iodoform plugs, but if properly placed, a plug does not itself pass into the lumen of the sinus but simply presses the walls of the sinus together.

Actual presence of an iodoform plug in the lumen of the lateral sinus serves no

useful purpose save that it stops a hemorrhage.

As far as the after-treatment is concerned, the original plugs placed in situ at the time of operation are left about five days at which time an attempt is made to remove them. If, at this time, any signs of bleeding occur at the ends of the sinuses, all attempts at their removal are stopped and the procedure is postponed for two or three days when it may be repeated. Usually at the end of seven or eight days these plugs may be removed at which time the wound may be treated as an ordinary mastoid cavity. It has been the observation of the author that these wounds invariably heal in a kindly manner.

Let us now go to a brief consideration of the operation on the jugular vein. Recently the question has been raised whether any operation on the jugular vein is of use in the prevention of the passage of infecting micro-organisms to the blood stream. It seems that on the soundest of clinical grounds the answer to this question is in the affirmative. What are the indications for operation on the jugular vein? If the condition of the patient permits, it is good surgery either to excise or ligate the jugular vein before operation on the mastoid or lateral sinus. If the condition of the patient is judged to be precarious, his life should not be hazarded by too strict an adherence to this rule and each case should be judged on its individual merits. In certain instances, especially in small children, the author cannot criticize the procedure of operating on the sinus and postponing ligation or excision of the vein according to the presence or absence of septic symptoms.

As regards the type of operation on the vein itself, the writer does not feel that he can be too arbitrary in deciding whether the vein should be excised or ligated. His individual preference is for excision of the jugular vein. In expert hands this operation can be performed with little, if any, more surgical trauma and shock than the operation of ligation. Furthermore, it has this decided advantage, that it is more certain of completely removing infected tissue. It is true that to-day we seem rarely to encounter veins containing a definite clot within their lumina, but almost invariably it has been found that the so-called normal veins removed by excision are the seat of a preliminary descending phlebitis in their outer coat. At the New York Eye and Ear

Infirmity this has been proven by microscopic section not only by the characteristic changes but by the actual presence of the bacteria in the same locality. Undoubtedly in the hands of a surgeon who has but an occasional opportunity to treat this condition the operation of ligation of the vein is a simpler one than that of excision. Possibly in certain cases occurring in women cosmetic considerations might be taken into account and the transverse incision used. Certain points in excision of the jugular vein may be of interest. The ordinary incision is made near the tip of the mastoid to the sternoclavicular articulation, the integument usually being incised at the first sweep of the knife. The platysma myoides is next encountered and should be carefully incised and search made for the anterior border of the sternomastoid muscle. Its anterior border should be clearly delineated. The common mistake is to go through the anterior part of the muscle and this mistake, if made, adds nothing but difficulties to the operation.

The round border of the muscle is delineated by sharp and dull dissection, and by a similar process its internal surface is carefully separated when the sheath containing the great vessels is seen, the jugular vein lying externally and being the most prominent. This is now carefully exposed throughout the entire length of the incision; the sheath picked up between two forceps and incised with the Mayo dissecting scissors. The vein is usually most easily found in the region of the omohyoid muscle from which locality it can be isolated upward in the above-mentioned manner. The vein should be isolated from below to some point above the facial vein. At this location a double ligature should be passed around the vein, care being taken not to include the vagus nerve which runs between and behind the great vessels. At this junction it is wise to issue a note of warning and a plea for extreme gentleness in handling the structures in this region. Tearing of the interior jugular vein in the region of its exit from the jugular foramen is a surgical accident that has serious consequences. The resulting hemorrhage in this region can only be controlled with packing and even then with difficulty. After the upper end of the jugular vein is ligated, the facial and thyroid veins are severed between double ligatures. The lower end of the vein near the omohyoid is ligated and cut away. There seems to be

no reason for putting unusually heavy ligatures around the inferior stump of the vein in this region. It has been the custom of the author to insert cigarette drains in the upper and lower angles of the wound and partially to suture the tissues and skin with interrupted sutures of plain cat gut and silk worm gut, respectively. The operative area may be considered infected from the descending phlebitis in the outer coats of the wall of the vein and usually breaks down.

In extremely sick cases, it is good surgery to leave the wound unsutured and to allow it subsequently to heal by granulation, the resulting scar being but slightly more unsightly than that of the sutured wound. In a severe case rarely does the wound in the neck heal by primary intention. In the operation of ligation the operative area is exposed by a similar though shorter incision. The vein is isolated above the facial and incised between double ligatures. For cosmetic reasons a transverse incision following the lines of cleavage of the skin may be contemplated. The author has never performed such an operation.

So much for the actual operative treatment of sinus thrombosis.

The author has never believed that a high temperature is a contra-indication to a generous regular diet, provided the patient has the appetite and his digestion is good. In feeding a patient, his likes and dislikes should be given the greatest consideration.

Blood transfusions in sinus surgery have contributed the greatest advance in the treatment of the disease for many years. Given before operation in a septic case, they prepare the patient for the surgical ordeal. Given after operation, they raise the resistance of the patient and stimulate the healing processes of the body. The author's experience has been with transfusions of whole blood. It seems to him that preference should be given to this method and citrated blood used only when whole blood is unavailable. The author believes that more aid is effected by repeated small transfusions than by one large one. This especially obtains in children. As a rule, transfusions from immunized donors, while theoretically of advantage, are impracticable on account of the time necessary to immunize the donor, and it has not been definitely proven that this theoretical advantage is an actuality.

This practically completes the surgical treatment of sinus thrombosis. Surgical

judgment of the physician will always play an important part in the ultimate successful outcome of the individual case. The question of manual dexterity of the operator has not been sufficiently emphasized in the treatment of this condition.

Before concluding, a few words should be said about sinus thrombosis occurring in a double mastoiditis. Life or death of the patient well-nigh hinges on a correct diagnosis. If the side of the sinus thrombosis is correctly diagnosed the patient has a chance for life. If the sound side is wrongly operated on, as a rule, a fatal outcome is inevitable. Possibly the method of determining the sinus involved should not be considered in this paper. The date of onset of either side and the severity of the pathological process uncovered at operation on either side must be given great consideration. In the long run possibly the best method is to uncover each lateral sinus and carefully inspect and weigh the significance of the pathological changes of the sinus wall. When the offending sinus

has been selected, it should be incised before ligation of the jugular vein. In this connection the Tobey-Ayer manometer test undoubtedly is of great value. The author cannot claim great familiarity with this method. His opinion, however, is that this method is of positive value when one or the other sinus is completely occluded, but unfortunately in most of his patients this is not the case. In this connection, also, the attending surgeon must remember that a double sinus thrombosis is a condition that can occur, and when chills and fever persist after the removal of a clot and ligation of the jugular vein in one side, this unfortunate but rare condition must be thought of.

In conclusion the author desires to state that the surgical treatment of sinus thrombosis is usually satisfactory when the diagnosis has been made promptly and the operative measures which have been discussed are performed with dexterity and good surgical judgment.

FINANCING HOSPITALS BY SWEEPSTAKES

We hear from time to time about the lucky folks who win fortunes in the Irish Hospital Sweepstakes, but we hear very little about what the hospitals get out of it. Well, it seems that they harvest only a small fraction of one huge sum paid in by the gullible public, less than one-fourth, in fact. The London correspondent of the *Journal of the A. M. A.* gives us some interesting figures.

The total amount subscribed to the last Irish Hospital Sweepstakes amounts to nearly \$15,000,000. Of this, about \$9,000,000 was expended in prizes and the hospitals received \$2,600,000, the remainder being government taxation and promoter's remuneration. To date about \$150,000,000 has been received for these sweepstakes,

mainly from other countries than Ireland, and about \$100,000,000 has been distributed in prizes. Great Britain has subscribed about two-thirds of the money and also received two-thirds of the prizes. Ireland's subscription amounts to only about 7 per cent of the total. The Irish hospitals have received in all about \$32,500,000. At first, aid was given only to the Irish voluntary hospitals; but the government now allots a portion of the proceeds to tax-supported hospitals. So great has been the amount received that it is now proposed to endow the hospitals, so that support will be forthcoming even if this novel source of income should dry up. It is also proposed to finance research work in Ireland by these sweepstakes.

DILLINGER'S FACIAL REPAIR MAN

If Dillinger's disposition could have been made over and "moulded nearer to the heart's desire" by sort of "lifting" process, it would have been a great public service, but his facial alteration, intended to baffle the police, is something quite different, and the authorities are looking for the surgeon who did it. This is very disturbing to the profession, remarks the *New York Medical Week*. It is unfortunate that a specialty which has rehabilitated countless thousands of unfortunates to the benefit of society as well as themselves can so easily be turned to the purposes of crime. One unscrupulous charlatan allies himself with criminality and projects a dark shadow of opprobrium which temporarily obscures the great good that plastic repair has done to many deserving citizens.

The Dillinger case, following as it does recent

newspaper publicity on the possibility of altering finger prints with skin grafting, emphasizes the necessity for organizing plastic surgery as a distinct specialty with strictly defined standards. Only in this way can the disreputable elements be curbed and plastic repair removed from the province of irresponsible quacks.

The police are apparently confining their search for Dillinger's helper to licensed surgeons. For all that is known, the offender may be a lay cosmetician who, by daily disregard of the Medical Practice Act, has become callous to the violation of all law. In any event, whether he is an authorized or unlicensed surgeon, his early detection is greatly to be desired as a warning to others whom greed might persuade into similar complicity in crime.

PHYSICAL THERAPY IN INDUSTRIAL INJURIES

JOHN B. STEVENS, M.D.

Syracuse

Physical therapy has established itself as an invaluable adjunct to the treatment of industrial injuries with some difficulty, with difficulty because industry demanded tangible results and, even more, results measurable from an economic standpoint. To those acquainted with the peculiar adaptations of physical therapy to the treatment of trauma and its sequelae, it may seem strange that this requirement was not easily met and recognition obtained.

Early the trouble lay in the tendency to utilize impressive but inefficient apparatus with little thought of the pathology present or the physiological effect of the modality in use. In the post-War period, with a wealth of clinical material, physical therapy, under government sponsorship in rehabilitation centers, reached a much more rational status. There was reasonably widespread dissemination of the knowledge of established principle and procedure. It was during this era that, led by a few outstanding physicians, this ancient but newly developed branch of medicine proved its worth in industrial injuries.

There was increased interest on the part of manufacturers of apparatus who embodied the old principles in more compact and more easily controlled machines and dressed them up in attractive and impressive cabinets and standards. Soon, however, there were extensive sales campaigns with the result that this expensive equipment which had to be paid for fell into the hands of medical men whose only standard of its value was contained in booklets and reprints furnished by the manufacturers. These pamphlets, as well as most of the current literature of the day, contained exaggerated claims of the therapeutic values inherent in the various electrical manifestations of these machines. Exploitation, perhaps unwitting by the tyro of this type, did much to discredit the advancing and valuable branch of medical science. The overemphasis by the untrained and by certain commercial clinics of the value of electrical currents and electrically generated heat of various types with neglect of the necessary exercises and manipulation remains to-day the glaring fault in physical

therapy as it is generally applied to industrial injuries. This fault happily is gradually being mended by the circulation of rational instruction through the County Medical Societies under the auspices of the Committee on Physical Therapy of the State Society as well as through the reports of the Council on Physical Therapy in the *Journal of the American Medical Association*.

The uses to which a knowledge of physical therapy may be put in the treatment of industrial traumata are numerous, but by far the most valuable service which it renders is in the preservation and restoration of joint function and it is with this subject that this paper has chiefly to deal. In considering the joint restrictions which are amenable to treatment—including prophylaxis in the term treatment—they seem to fall roughly into four groups on the basis of pathology involved.

(1) That group in which there is trauma to joint surfaces without essentially disturbing the mechanics of the joint. Here hemorrhage into the joint cavity or the covering of the apposed damaged surfaces with fibrinous exudate tend to form dense adhesions if immobilization is sufficiently prolonged. Concomitant tearing of the ligaments about the joints—almost always present—repairs during the immobilization period with excessive scar tissue formation.

(2) In those conditions in which the joint proper is not damaged but the extremity is immobilized by involuntary muscle spasm or therapeutic fixation, circulatory hypostasis and edema tend to produce peri articular fibrosis.

(3) Soft-tissue infections leave inflammatory exudates, the organization of which produces fibrosis and amalgamation of the tissue planes with consequent limitation of motion.

(4) Extensive destruction of soft tissues, particularly in the region of joints, by mechanical or thermal agents is followed by the production of dense scar tissue and the formation of adamant contractures.

Obviously, in all of these, a great deal

of the undesirable effects can be prevented by maintenance of adequate circulation and motion of the joints during the period when adhesions and fibrous tissue infiltration are in the process of formation. We are now treading on a decidedly controversial territory. Extremists on both sides of the problem have produced brilliant results at the risk of costly failures. The proponent of very early motion maintains the flexibility of joints, often at the cost of malunion of fractures and joint instability from insufficiently repaired ligaments. His strongest critic obtains perfect anatomical restoration after long immobilization, frequently at the expense of permanently limited function. We turned then to the middle course. The encouragement of motion in joints of the extremity not included in the fixation apparatus at least preserves function in these joints. This motion and activity of muscles also undoubtedly plays a part in promoting repair by maintaining adequate circulation as has been so convincingly pointed out by Boehler, of Vienna. Further, it has been demonstrated that once fibrous fixation of bone fragments has been obtained and osteogenesis started—arbitrarily in adults in fourteen to twenty-one days—careful motion of the joints on either side of the fracture can be carried out without essentially disturbing alignment of the fragments or endangering union. Recent improvement in methods of immobilization has done much to simplify this procedure.

That which holds true of fractures is also applicable to soft tissue injuries, notably sprains. Mechanical ingenuity in the application of strappings and prostheses to put damaged ligaments at rest in as perfect apposition as possible without complete immobilization of joints leaves the way open for the early application of physical therapy measures.

The treatment of infected parts in packs or baths containing warm hypertonic solutions and the insistence on early voluntary motion leaves surprisingly little restriction of joint range at the subsidence of the infection, particularly if elevation and support of the extremity in a position of physiological rest is practiced between periods of activity.

Immobilization of joints in a position to prevent scar tissue contractures after destruction of tissue by physical and thermal agents greatly simplifies the ultimate rehabilitation of these joints, even

though early motion may not be indicated because of its deleterious effect on epithelialization.

A considerable amount of space has been devoted to what might properly be termed prophylactic physical therapy because it is to-day the most generally neglected and perhaps the most valuable. The physical therapist, however, has usually little opportunity to apply these foregoing principles to industrial injuries unless perchance he heads the physical therapy department in a hospital with a more than usually enlightened surgical staff. The large part of his practice consists of postsurgical cripples whose treatment up to that time, so far as joint function is concerned, has been good, bad, or indifferent. However, by this time, as a rule, the wounds are healed, the infection controlled, or the bones united; the case has been referred for relief of pain, swelling, and restriction of motion.

The author has no conceit that he has anything new or startling to offer in the way of treatment of these conditions but opportunity has been granted him to treat a fairly large number of cases and to observe both the immediate and late results. At the same time, he has examined numerous similar cases treated elsewhere by physical therapy of various types and some in which no physical therapy whatever has been given. This has resulted in a fairly definite evaluation of the methods in common use to-day and a development of a routine of treatment based on the pathology present. This treatment seems to have produced maximum clinical improvement in the least possible time.

The equipment need not be elaborate. The whirlpool bath, both arm and leg, diathermy machine, infra-red radiator, and galvanic-current source will meet all requirements. We will consider for a moment the known physiological effects of these modalities: The whirlpool bath as a preparation for massage and manipulation has, in our opinion, no rival in the restoration of normal circulatory balance to a recently immobilized extremity. Run at 110° ordinarily for 45 minutes on the lower extremity and 30 minutes on the upper extremity, it produces an intense skin hyperemia. The comforting warmth and the gentle stimulation of the sensory nerve endings in the skin by the circulation of the water and bursting of the air bubbles produce in most cases prompt relief of pain. Relaxation of spastic muscles is evident to the pa-

tient as it is to the observer. Dilatation of the deep vessels has been described and evident increase in the volume of the limb bears this out clinically. These effects, combined with the buoyant action of the water, encourage active motion of the affected joints even in the most timid, a result difficult to obtain in many instances by any other modality.

It is desirable to have the whirlpool baths in a well-ventilated but draftless room or cubicle as the heat and humidity are uncomfortable to all patients and intolerable to some. Much of the discomfort of the heat and vapor may be eliminated by providing for the bath a removable cover with a cut-out for the extremity. The patient should be completely divested of his clothes and a gown provided so that he need not leave the treatment room in perspiration-soaked clothing. An abundance of drink-ink water should be available to him.

The high frequency current has been most valuable in promoting the absorption of effusions in joints and bursae. When heat and hyperemia are required to promote repair in deep structures, diathermy serves the purpose. However, the pathological area must be sufficiently circumscribed to permit its inclusion by the electrodes placed diametrically opposite each other. The double cuff and the cuff and plate methods in our hands have not been efficient. The choice of the electrode material is a matter of personal preference and experience. We have used a metal mesh over a moist rubber sponge held in place by gentle compression by an E clip when practical; otherwise, the mesh with the interstices filled in with electrolytic mucilage. In the second instance, the upper electrode is held in place by adhesion and gravity and the lower is held against the skin surface by a partially inflated basketball bladder upon which the extremity rests.

We have used infra-red to produce relaxation and hyperemia in locations where the application of diathermy or whirlpool is impracticable or in cases where open wounds or skin conditions preclude the use of whirlpool. We have little preference as to the source, whether it be an incandescent bulb or a dark-body radiator. It should be applied for a period of 45 to 60 minutes at the intensity most comfortable to the patient.

Both negative and positive galvanism have occasionally been found useful. The negative pole applied for 20 to 30 minutes

over an area of superficial scar tissue produces softening of the tissue in preparation for stretching, massage, and passive motion; the positive pole theoretically is sedative in its effect and produces organization of tissue. Occasionally we have had extremely satisfactory response in using positive galvanism for both of these effects over torn ligaments. Unfortunately, the results have been anything but consistent.

These modalities are definitely useful as preparation for massage and passive motion but will be found of little value when used alone. The technician skilled in massage and manipulation is the sine qua non of the physical therapy set-up. The physician may diagnose the pathology and prescribe the proper treatment, but the efficient, conscientious fulfillment of it is more or less out of his hands. Experience has taught us that a single technician is physically capable of efficiently handling sixteen to twenty average cases of joint restriction in a day. To attempt to do more is to do so at the risk of negligent or careless handling.

The types of massage are well known. Most valuable we have found to be a slow effleurage as deep as is comfortably tolerated, carried, of course, centripetally. Circular thumb massage skipping from place to place in an effort to "rub away the pain" we have found to be of little value. The only departures from this which come to mind are in the stretching thumb massage used to render more ductile superficial scar tissue and the kneading or petrissage so useful in producing relaxation about the shoulder girdle.

Passive motion must be given carefully and with due discretion. The ability to give passive motion properly is the mark of the accomplished technician. The patient must be completely relaxed and we require the reclining position in all but forearm and hand cases. Not only must the patient be relaxed but the technician must be in a comfortable position with the best leverage possible to avoid the introduction of muscular quivering from sustained effort. Passive motion should be carried out slowly and the joint maintained for an appreciable period at the limit of excursion tolerated by the patient. A happy medium must be struck in the force with which this passive motion is applied. To accomplish results ordinarily it must be somewhat uncomfortable. If discomfort lasts for more than two hours after the application of the passive force or if there is evidence of inflam-

matory reaction the following day with consequent decrease in joint range, gentler passives must be given. A good technician soon learns to gauge the proper limit at which to stop to gain the utmost improvement. A single passive excursion daily supplemented by active motion produces the optimum effect. The "pump-handling" type of passive succeeds only in irritating the joint and causing muscle spasm. It should never be resorted to. At times it is impossible to gain the relaxation of the patient and in some instances the opposition of the patient's muscles is too great to overcome. This is particularly true in dorsiflexion of the ankle and in flexion of the knee. Where there is strong resistance to dorsiflexion at the ankle we have adopted a simple method of having the patient stand two or three feet from a wall; facing it he places the palms of his hands against the wall and, flexing his elbows, permits his chest to approach as near to the wall as possible without lifting the heels from the floor, maintaining that position for from two to three minutes. A prolonged, steady passive flexion of the knee may be obtained by flexing the thigh with the patient reclining and putting a padded support in the popliteal space. Weights are then gradually added at the ankle until the tolerance of the patient has been reached. These weights may be allowed to remain until the resistant quadriceps has been fatigued.

So far, everything has been accomplished for the patient. In order to avail himself of the advantage already gained, wasted muscles must be built up and active use encouraged. This may be accomplished by formal exercises or by adequately supervised occupational therapy. A combination of the two is most desirable. However, an ingenious occupational therapist can devise interesting tasks which will include adequate exercise of the atrophied muscles as well as motion of the affected joints without making the process unduly onerous to the patient.

The average compensation patient lends himself very easily to prolonged treatment. It is wise to know when to stop; it is also advantageous to be able to present to the employer or insurance carrier who pays the bills an accurate record of the accomplishment. This is best done by examination of the patient at regular intervals during which time the appropriateness of treatment can be checked and the increase in joint range accurately measured. For the measurement of joint range, we have availed ourselves of a simple method, utilizing a flexible lead tape which is made to conform to the angle made by the joint and the angle then measured on an ordinary protractor.

If the proper procedures have been used, we have assumed that lack of appreciable progress over a period of two weeks indicates that the limit of improvement through treatment has been reached or that some systemic disturbance, such as absorption from toxic foci, is halting progress. Consideration of this important phase does not fall within the scope of this paper.

CONCLUSIONS

1. Joint restriction can often be prevented by early motion which stimulates rather than hinders repair.

2. The pathological process entering into the production of stiff joints must be recognized and the modality, the physiological effects of which are suited to its relief, applied.

3. The use of apparatus has definite value but only as a preliminary to skillful manipulation at the hands of the physician or well-trained technician.

4. Active use of the part, preferably under the supervision of an occupational therapist, is a necessary supplement to other physical therapy procedures.

5. Accurate records of accomplishment are highly desirable and treatment should not be prolonged beyond the period during which definite improvement takes place.

624 CHIMES BLDG.

RURAL HEALTH NEEDS NEGLECTED

Less than 600 of the 2,500 rural communities in the United States are provided with even a whole-time health officer, and not more than 100 of the counties now under the direction of whole-time health officers have what might be considered reasonably adequate health service. So Surgeon-General Hugh S. Cumming, U. S. Public Health Service, told the annual conference of Health Officers and Public Health Nurses at Saratoga

Springs. What is more, he added, less than 25 per cent of our rural population have at the present time adequate facilities for health protection. This problem is beyond the power of state health department personnel to cope with, he declares, and he believes that it is necessary that the local people themselves participate more or less directly in providing the funds for the maintenance of health service and in choosing those who shall look after their public health needs.

STUDY AND TREATMENT OF AMENORRHEA

C A HEDEN MD

From the Department of Obstetrics and Gynecology, University of Rochester School of Medicine and Dentistry, Rochester, N. Y.

Outstanding endocrine disorders, of which menstrual disturbances are a part, have been known for many decades, but until recent years no systematic study of endocrine dysfunctions has been attempted using all available diagnostic laboratory procedures. The rapid advances in the field of animal sex physiology, particularly the isolation of the hormones of the ovary, and the preparation of anterior pituitary-like hormone extracts from the urine of pregnancy, has stimulated interest in menstrual disturbances. In clinics throughout the world applications of the new sex physiology are being instituted with varying results, which of course means that the problem is not yet solved.

The object of presenting a study of amenorrheas, as a part of menstrual disturbances, is, first, to outline a method of study for purposes of diagnosis, a method which differentiates those of endocrine and nonendocrine origin and, second, to give the present-day status of treatment for those of endocrine origin.

The method of study of menstrual disturbances is taken in part from the comprehensive endocrine contributions of Rowe and Lawrence¹ and in part elaborated at the Strong Memorial Hospital. Rowe and Lawrence have correlated the clinical histories, physical findings, and all known diagnostic laboratory procedures on some four thousand cases of endocrine disease and from these data have classified endocrine disorder according to the gland primarily involved. It is necessary, according to these authors, that a complete history be taken, a thorough physical examination, and the usual laboratory procedures be done to rule out any acute or chronic disease and any blood dyscrasia, since they often simulate an endocrine picture. If these procedures reveal no disease, then the patient is studied for endocrine disturbances. It is necessary in cases of amenorrhea to rule out anatomical pelvic causes and early pregnancy.

If the above findings reduce the causes of amenorrhea to an endocrine disturbance, then the next step is to determine which gland is primarily involved. To accom-

plish this, the following tests and chemical studies are performed: a basal metabolism and galactose tolerance test are done, a sample of venous blood is taken for chemical analysis, particularly uric acid, creatinine, and sugar, the urine is analyzed for the presence or absence of various constituents noted later, accurate visual field and blind-spot measurements are made and the fundi are examined for color, contour, and abnormalities. Sella turcica x-rays are not taken unless indicated by neurological signs. A few of the tables from the work of Rowe and Lawrence on the differential diagnosis of endocrine disorders will serve to bring out the main points of significance. These tables give tendencies and not exact figures. The reader is referred to the original publications for the latter.

In their table on urine measurements (Table I) there is evidence of renal involvement associated with thyroid and adrenal failure as revealed by the presence of casts and albuminuria. Rowe and Lawrence claim that in the case of the thyroid the evidence of renal disease is that of a pseudonephritis, while that of adrenal failure is associated with a true nephropathic condition. Sugar is present in the urine of adrenal and ovarian failure. Urobilinogen is usually present in pituitary hypofunction. The remaining urinary findings closely parallel the blood chemistry and need not be considered at this time.

TABLE I—URINE MEASUREMENTS—ENDOCRINE HYPOFUNCTION

Observation	Pit	Thy	Ov	Test	Adr
Volume	N or >	N or >	N or >	N or >	N or >
Elimination	N or >	N or >	N or >	N or >	N or >
Albumin	N or >	N or >	N or >	N or >	N or >
Casts	N or >	N or >	N or >	N or >	N or >
Sugar	Rarely	Rarely	N or >	N or >	N or >
Indican	N	N	N	N	N
Epithelial debris	N	N	N	N	N
Urobilinogen	N	N	N	N	N
Nitrogen elimination	N	N	N	N	N
Residual nitrogen	N or >	N or >	N or >	N or >	N or >
Phthalein elimination	N	N	N	N	N
Salol elimination	N	N	N	N	N
Urea curve	N	N	N	N	N
Urea index	N	N	N	N	N

In the table on blood chemistry (Table II) it should be noted that the nitrogen constituents and sugar are of definite diagnostic value. Note the increase in the uric acid content in pituitary hypofunction; the increase in N.P.N. and urea and a low normal sugar for hypothyroidism, and an increase of all nitrogen constituents of the blood except creatinine and a marked decrease in sugar in adrenal insufficiency. In the endocrine hypofunction the blood morphology is of little value so far as differential diagnosis is concerned, except in pituitary failure where there is a lymphocytosis and eosinophilia. The blood picture associated with adrenal insufficiency is that of an anemia.

TABLE II.—BLOOD CHEMISTRY—ENDOCRINE HYPOFUNCTION

Observation	Pit.	Thy.	Ov.	Tes.	Adr.
Nonprotein nitrogen ..	N	>	N	N	>>
Urea nitrogen	N	>>	N	N	>>
Uric acid	>	N	N	N	>
Creatinin	N	N	N	N	>
Residual nitrogen	N	N	N	N	>
Sugar	N	Low N	N	N	>

The table on basal metabolism (Table III) and sugar tolerance reveals relative changes. In the case of hypofunction of the glands it should be noted in all cases that the basal metabolism is decreased; greater in the thyroid, next in the adrenal, and the pituitary and ovarian are about alike. The tolerance for sugar in the pituitary cases is increased, in the thyroid cases it is about normal, in the ovarian hypofunction it is increased, and it is decreased in the adrenal cases. The opposite holds true, of course, for hyper-function of the pituitary gland and thyroid.

TABLE III.—BASAL METABOLISM AND SUGAR TOLERANCE ENDOCRINE HYPOFUNCTION

Observation	Pit.	Thy.	Ov.	Tes.	Adr.
Basal rate.	<	<<<	<	N or <sl	<<
Sugar tolerance	>>>	N or >	<<	N	<<<

HYPERFUNCTION

Observation	Pit.	Thy.
Basal rate.....	>	>>>
Sugar tolerance	<<<	N or <

By way of illustrating as simply as possible (Table IV) some of the diagnostic data, Rowe and Lawrence have compiled their findings on young adults each with about the same degree of glandular failure. They give this data merely as a setting in

ideal uncomplicated cases, and these must be used with due caution when interpreting and applying them, so far as other cases are concerned. Each case must be considered individually.

TABLE IV.—ILLUSTRATIVE DATA IN HYPOTHETICAL IDEAL CASES

	Pit.	Thy.	Ovary	Test.	Adr.
Basal rate.	—25%	—45%	—18%	—6%	—35%
Pulse	68	50	78	72	76
Respiration.	14	10	16	15	15
Temperature	98.2°	97.0°	98.2°	98.4°	97.8°
Blood pressure, systolic	110	100	98	112	90
Blood pressure, diastolic	70	60	65	75	60
Sugar tolerance	+100%	±0%	—50%	±0%	—83%

It is difficult in some instances to differentiate between pituitary and ovarian failure by the above procedure of Rowe and Lawrence. Siebka^{2, 3, 4} has shown in cases which he classified as primary amenorrheas that there was a minimal amount of estrin in the urine. This finding has been confirmed in our clinic and in addition we have found that in amenorrhea due to pituitary failure the urine contains considerably more estrin; hence we have added the determination of urinary estrin to the procedure of Rowe and Lawrence. The method in brief is: a fresh 24-hour sample of urine is collected, acidified, and the estrin is completely extracted with benzene, according to a method previously published. The benzene is evaporated and the residue containing the estrin is dissolved in a definite amount of oil; this extract is injected into castrated female rats in graded doses to determine the daily amount of urinary estrin the patient excretes. In addition, in this clinic a sample of the endometrium is obtained by means of a small tubular curet, for purposes of correlation. This is not possible in all cases.

Following the above procedure, 27 cases of amenorrhea of endocrine origin have been studied and treated for over a period of at least 6 months to 2 years. These cases represent those of a true endocrine disturbance unassociated with any other disease, except as will be noted. The amenorrheas divide themselves naturally into primary and secondary. The primary group can be further divided, based on the size of the genitalia, first, into those with infantile type of genitalia and second, those with normal-sized genitalia. The following protocol illustrates the type of patient with

infantile genitalia. Three such patients have been studied.

The patient No. 38799 is a 23-year-old married woman who menstruated once at the age of 14 and who has not menstruated since, except for occasional spotting during 1 year. There is nothing in the present or past history of any diagnostic significance and the only positive findings are a moderate obesity and infantile genitalia. The laboratory studies were within normal limits except for a low blood sugar and an entire lack of urinary estrin in several samples of urine. The cervical canal was so small that it was impossible to obtain a sample of the endometrium. The patient was given 1,200 rat units of theelin over a period of 12 days. She did not menstruate nor did she have any premonitory symptoms of menstruation. Pelvic examination showed no change in the size of the uterus. Following the method of Kaufmann⁵ she was given 10,000 rat units of progynon intramuscularly twice weekly for 5 doses, making a total of 50,000 rat units. She menstruated 7 days after the last injection for a period of 5 days. Menstruation is used in the sense of uterine bleeding only. Over a period of 5 months she received a total of 242,000 rat units of progynon, during which time she menstruated on several occasions. Pelvic examination at the end of this treatment showed no increase in the size of the uterus. It was still impossible to enter the cervical canal with the small tubular curet without anesthesia.

Kaufmann⁵ treating amenorrhea with progynon in this type of case, that is, with infantile genitalia, obtained an enlargement of the uterus in 2 out of 5 cases as determined by examination. In one of his cases the patient was given 300,000 mouse units of progynon in 3 weeks following which she menstruated for 2 days. The treatment was continued until the patient received 600,000 mouse units or 120,000 rat units. The uterus before treatment was the size of a hazel nut and according to the author, it had reached twice the size at the end of the treatment.

His second case received 600,000 mouse units or 120,000 rat units during 6 weeks during which time she menstruated for 3 days. Treatment was continued, however, until she received 800,000 mouse units or 160,000 rat units in a period of 9 weeks. The uterus grew to twice its original size. The other 3 cases of Kaufmann in which no enlargement of the uterus occurred, received as much or more of the hormone preparation.

By administering progynon in the doses mentioned to this type of patient and following it with proluton, a preparation containing progesterin, the onset of the bleeding can be delayed for a number of days. The details of this procedure are to be published in a forthcoming paper. It is our experience in this type of case that so long as one gives substitution therapy, as described, menstrual bleeding will ensue but when the medication is discontinued, the patient will cease menstruating. Since it is the opinion of the author that the ovaries are secondary to the other endocrine glands of the body, particularly the pituitary, one must look elsewhere for the final treatment. If this type of patient could be seen before or at puberty, and if the proper growth-promoting and gonad-stimulating hormones of the pituitary gland were available for

therapy, then some hope for help could be entertained.

In the second group of primary amenorrheas, that is, those of normal-sized genitalia, estrin therapy may be of some value. This type of case is rare and the present protocol will serve to illustrate the one case we have studied.

Patient No. 82307 is a 27-year-old married nulliparous woman who menstruated first at the age of 17 and then only about once a year. She had mumps in childhood and a question of thyroid hyperfunction when 21, for which she received Lugol's solution. The patient gives a multitude of symptoms which cannot be accounted for. Positive findings of the physical examination are marked hirsutism with male distribution of pubic hair, a slight exophthalmos, left ventricle preponderance, and hyperactive reflexes. Laboratory findings showed a basal metabolism of minus 18, a slightly increased tolerance for sugar. She had about 8 rat units of estrin in her urine. The blood chemistry showed nothing of significance. Blood morphology showed an increased lymphocytosis. She was given 2 courses of progynon treatment in a period of 2 months, a total of 100,000 rat units, and since cessation of treatment she has menstruated twice spontaneously.

Kaufmann⁵ reports 2 cases of primary amenorrhea with normally developed genitalia, treated with both of the ovarian hormones, but was not able to induce spontaneous menstruation in either after cessation of treatment. Gauss and Buschbeck⁶ following Kaufman's procedure using both ovarian hormones, were able to initiate a spontaneous menstrual cycle in a patient with secondary amenorrhea who had not menstruated for 10 years. Whether our reported case is a true hypogonad stimulated by ovarian therapy or whether there was interaction between pituitary hormone and the injected ovarian hormone causing a normal menstrual cycle, or whether the whole picture is mere coincidence, remains to be seen.

In general, it can safely be said that the treatment of primary amenorrhea, with either or both of the hormones of the ovary, is satisfactory so long as the medication is continued according to the method outlined by Kaufmann, but when therapy is discontinued, menstrual bleeding ceases. Further search must be made to find the substance which will institute and maintain a spontaneous cycle.

The group of secondary amenorrheas responds much better to therapy. These cases will be presented according to the gland which seems primarily responsible for the amenorrhea based on the method of study.

Eight cases of definite hypothyroidism have been studied, 4 of whom have been successfully treated, 3 of whom have had menstrual periods with varying degrees of

irregularity, and 1 of whom has been a complete failure.

The following protocol is that of one of the successfully treated cases.

Patient No. 80978 is an 18-year-old single female who menstruated regularly and normally every 28 days until 1 year before being seen in clinic. Nothing could be elicited in the past or family history of any diagnostic significance. There was nothing in the clinical history suggesting an endocrine disturbance except amenorrhea. The physical examination is entirely normal. A diagnosis of hypothyroidism was made on laboratory findings which showed a basal metabolism of minus 19, normal sugar tolerance test, normal blood chemistry except for a low normal blood sugar. The patient was given maintenance doses of thyroid gland for 2 months. The basal metabolic rate was brought to within normal limits. For the next 5 months she menstruated normally without medication.

Since hypothyroidism may be secondary to infection, one must continually be alert for its detection. One of our cases, No. 54290, ceased menstruating with a marked iritis and uveitis 3 years ago. When the infection had subsided, she was given maintenance doses of thyroid and began to menstruate regularly. While under treatment she developed an upper respiratory infection and her menstrual periods ceased until this infection cleared up. A basal metabolic rate done before her acute upper respiratory infection was normal was minus 24 after the infection subsided. The other laboratory findings were within normal limits.

Three of the partially successful cases may be due to the fact that they have not yet received the maintenance dose of thyroid preparation. Since there is no relationship between the basal metabolic rate and the amount of thyroid gland administered, each patient must be treated individually, and it is felt that when proper maintenance doses are reached, menstruation will ensue.

We have had a case of mild hyperthyroidism, No. 51419, who had amenorrhea for 6 months following a perfectly normal cycle. The clinical history and physical findings were entirely negative except for hyperactive reflexes and an accelerated pulse. The laboratory findings were all normal except a slight increase in the basal metabolic rate. The patient was given small doses of Lugol's solution for 2 months when the cycle became normal, and she has since been without medication.

We have had 4 cases of hypopituitary function, 2 of whom have been successfully treated and 1 partially successful. The last case was not treated because of a positive

Wassermann since it may be that her amenorrhea is secondary to her leptic condition.

One of the successfully treated cases, No. 56128, was an 18-year-old single girl who established a normal menstrual cycle at the age of 12, and has had intermittent periods of amenorrhea up to 9 months for the past 2 years. She had the usual childhood diseases. There was a loss of about 35 lb. of weight coincident with amenorrhea. The general physical examination was essentially normal. The laboratory findings revealed a basal metabolic rate of minus 6, and increased tolerance for galactose and 120 rat units of urinary estrin. The blood chemistry was normal except for a slight increase in uric acid. There was a 40 per cent blood lymphocytosis. The urine was negative except for a 2 plus urobilinogen. The patient was given 14 gr. enteric coated anterior lobe of the pituitary gland daily for 3 months. She apparently established a normal cycle after the second month of treatment and she has had 3 normal cycles since without medication.

In the other apparently successfully treated case the patient had 3 normal menstrual cycles while on medication. Medication was discontinued for 3 months, during which time the patient ceased menstruating. When resumed for a period of 2 months, the patient had 1 normal cycle. She has not been followed since.

The other successfully treated case had 4 normal cycles following medication with anterior pituitary gland by mouth following a period of amenorrhea of 1 year. Previously her cycles were every 2 to 3 months.

Organotherapy by mouth, particularly pituitary gland, has been advocated by some, while others consider it valueless. Most observers feel that the preparation given by mouth is without effect. However, Rowe and Lawrence⁷ have been able to obtain some clinical results by using large doses, up to 35 gr. daily, of desiccated anterior lobe of the pituitary gland. It has apparently been successful in some of the cases of hypopituitarism. We have been able to establish a normal menstrual cycle with enteric coated desiccated anterior lobe of the pituitary gland by mouth, and it has proved of value in certain types of intermenstrual bleeding, published elsewhere.⁷

We have had 2 cases of hyperpituitarism diagnosed by our method of study. Both of these cases have been failures so far as initiating menstruation is concerned. Our only means at present of treating this type of case is by x-ray to the pituitary gland. This has been done in both cases. In 1 case the laboratory tests had been brought to

their normal levels but menstruation has not resulted. Rowe and Lawrence have also noted that x-ray therapy to the pituitary gland is without clinical effect but it may alter the laboratory tests.

In studying secondary amenorrheas there is a group of cases which are difficult of diagnosis so that any rational therapy is impossible. We have had 2 such cases. Early menopause falls into this group and at present nothing can be done for this type of patient.

DISCUSSION

Viewing the field of menstrual disturbances, so far as therapy is concerned, as a whole, the results are promising, but the problem is far from solved. Caution should be exercised in too hasty application of animal experimental findings to clinical problems. Much careful work needs to be done.

The interrelationship of the various glands to the ovary is still unsolved and the interrelationship between the hormones of the ovary so far as the human castrate is concerned, is not known. These problems are now being studied. As yet there is no growth-promoting or gonad-stimulating hormone of the pituitary gland available for clinical use. The pituitary like hormone made from the urine of pregnancy should be used with caution since its action in the human is not known. Recently Engle⁸ has shown that this type of preparation causes a cessation of ovarian activity with atresia of the large follicles and hyalinization of the small follicles in the monkey, while anterior lobe or extractions of the anterior lobe cause follicular growth.

SUMMARY AND CONCLUSIONS

1 A method of study of amenorrheas is presented which has for its purpose the diagnosis of the endocrine gland primarily involved after all diseases simulating endocrinopathies have been ruled out.

2 Twenty seven cases of amenorrheas of endocrine origin are presented.

3 The primary amenorrheas with infantile genitalia respond to estrin therapy only so long as the therapy is continued. No permanent enlargement of the uterus is noted in any cases of this type. Primary amenorrheas with normal sized genitalia may respond spontaneously after treatment with estrin or progynon.

4 Secondary amenorrheas may be hypothyroid or hyperthyroid or pituitary. They respond fairly well to the proper medication when given in sufficient doses except the cases of hyperpituitary function.

5 There is a certain group of amenorrheas which we have not been able to diagnose, and therefore rational therapy could not be instituted. Early menopause must be considered in the group of secondary amenorrheas.

The theelin was gratuitously supplied by Parke, Davis and Company, and the progynon by the Schering Corporation.

STRONG MEMORIAL HOSPITAL

JUMPY SURGICAL PATIENTS

Nervous high strung people are not the best surgical risks in the world, as many surgeons no doubt are aware. It may be from sad experience that Dr Gordon Taylor prepared a paper on Bad Surgical Risks which he read before the surgery section of the British Medical Association in London at its recent meeting. Any surgeon of experience he observed will have convinced himself that the psychological undesirables considered from an operative viewpoint constitute as numerous and motley a collection as the Gilbertian list in *The Mikado*. That surgeon will be wise who refrains from any operation of convenience upon those who require much persuasion or overpersuasion. He should be aware of the apprehensive patient, and he will also regard with anxiety the man with huge piles of books on the tables at each side of his bed.

the man with the rapid pulse and the stack of French novels around him and likewise the individual who is reading his paper upside down!

An eventful recovery or worse may be confidently predicted for those who change their religion the night before in operation and for the politician or potentate who keeps the theater waiting while the final lines of his autobiography are completed. These types may well be regarded as bad risks before operation but the appearance of these eccentricities or unusual whims in a patient after surgery are sign posts of ominous portent. Unfortunately this attitude of mental unrest often develops only after an operation and the operator may be taken unawares. It is commonplace experience that clergymen, doctors, nurses, actors, and those of an artistic temperament are poor surgical risks.

CASE REPORT

CALCIFIED VESSELS OF THE LOWER EXTREMITIES OF A
YOUNG MAN

ABRAHAM S. ROTHBERG, M.D.

New York City

Calcification of blood vessels associated with arteriosclerosis in the aged or with diabetes in the presenile period occasions no comment. In the age group from forty to fifty Morrison and Bogan¹ have demonstrated calcium in the arteries in 63 per cent of a group of diabetic patients as compared with 36 per cent in a group of non-diabetics.

Below the age of forty such findings appear to be uncommon in nondiabetics. Personal inquiry among orthopedic surgeons and medical men who see many cases of circulatory disturbances has brought the answer that the youngest of these cases within their recollections were about forty.

colitis for five years and also of some endocrine disturbances.

Surbeck² reported a case of an autopsy of a child three days old, in which in the pericardium was found a diplococcal infection associated with nephritis and lobular pneumonia. Syphilis was ruled out by anatomical investigation, by search for spirochetes in the liver, and by Wassermann reaction in the mother. Calcification of the vessels was found in the aorta, with all its branches, coronaries, carotids, femorals, vessels of the extremities, the pulmonary and all its branches. Also the kidneys, suprarenals, and the ovaries had calcium deposits.

A case of calcification at the age of 26 with-

Figure 1

Figure 2

Syphilis as a cause of calcium deposit in blood vessels is well-known and may apparently be operative at a very early age. Verocay³ reported an instance in a girl of six months who suffered from congenital lues in whom was found extensive calcification of the arteries including the peripheral vessels.

Other factors, such as general debility from chronic colitis, may apparently account for early calcification. Bogar of the New England Deaconess Hospital in Boston has advised the writer in a personal communication that the youngest nondiabetic with calcified vessels seen in his clinics was a girl of eighteen, the subject of

out diabetes or syphilis or other known or demonstrable etiological factor seems rare enough to deserve recording.

The present case is that of a young man (J.B.), born in Russia of Semitic parents, single, an accountant, who consulted the writer in May 1931 when his age was 26. He complained of dull pain of about three years' duration over the medial surface of the right calcaneal region. There was also pain about the right ankle and knee; and later a "cold" sensation alternating with a "burning" sensation in the right thigh. The pain and hot and cold sensations bore no relation to weather or seasons and were relieved

in considerable measure by walking and exercise.

There was nothing significant in the family history. There was no record of illness of note other than the usual childhood diseases. He smoked about three or four cigarettes a day at most, some days none at all.

Physical examination, general, neurological, and local, was negative except for a hypotension, 104/60, and slight tenderness over the area of pain. The dorsalis pedis and posterior tibial pulsations were readily obtained. Laboratory tests for serum phosphates, calcium, sugar, creatinine, and urea nitrogen were all within normal limits. The blood Wassermann was negative. Tests for parathyroid functions were negative. X-rays taken by Dr. Maurice M. Pomeranze on July 21, 1931, showed calcified vessels of right ankle and foot. (Figs. 1 to 3.)

He passed from observation until March 1934 when examination revealed no changes and pulsation in dorsalis pedis and posterior tibial was again easily obtained. The pain on the right side was worse and for a year and a half a similar

Figure 3

pain had appeared on the left.

As a check on the earlier radiological findings, Dr. John R. Carty of the New York Hospital took films by the low voltage technic designed to emphasize soft tissue changes on June 16, 1934. He reported: "Films of the extremities show marked calcification of the larger blood vessels below the knee. There is a slight amount of calcification about the vessels of the knees. The vessels about the elbows show no definite evidence of calcification. We have then a widespread arteriosclerosis with calcification, more marked in the legs and feet." Figures 4 to 6 show three of these films

SUMMARY

A case is presented of calcification of blood vessels of the lower extremities, proven by x-ray, at the unusually early age of 26, in which no cause could be assigned for the changes. It has also been noted that, contrary to the rule in thrombo-angiitis obliterans, this patient experienced relief of discomfort in walking.

CASE REPORTS

FAMILIAL PEPTIC ULCER

A Family History

ARTHUR M. DICKINSON, M.D.

Albany

The exact etiology of peptic ulcer is still a matter of speculation. Many theories have been advanced by the various students of the problem.

The following brief case histories of five siblings with proven peptic ulcers are presented to record what appears to be more than a simple coincidence. The five children who had proven ulcers did have the acute subcostal angle considered by Draper to be of significance. The entire family were of the tall, thin type which would suggest the acute subcostal angle to be a family characteristic. It will be noted that all members of this family were heavy eaters.

We acknowledge the transmission of physical and mental characteristics through the genes; this family presents definite evidence of transmission of physical characteristics. Therefore, it is not possible that some factor or factors, at present unknown, which play a part in the causation of peptic ulcer have likewise been transmitted.

HISTORY OF THE FAMILY

The father died at 68 of pneumonia; he had no stomach trouble. The mother is alive and well, age 65; she gives no history of stomach trouble. There were 11 children born of these parents, 6 boys and 5 girls. Two of the male siblings have died. James T., the individual reported in Case 1, died at the age of 34 of cerebral abscess. Frank T., Case 4, died following operation for peptic ulcer. The female children are alive and well with no history of stomach trouble except Helen T., Case 5. All but one of the males and two of the females live in their own homes. The entire family were remarkably well as children. All (except one) have bright red hair, are nervous and high strung. All members of the family, parents included, were heavy eaters, especially of bread, meat, and potatoes. One male sibling (Case 3) abuses alcohol. All members of the family are of the tall, thin type.

Following is a brief history of each of the five siblings who are known to have had peptic ulcers.

CASE 1.—James T., age 28, male, entered the Albany Hospital Oct. 27, 1920, with a history of indigestion of 8 years' duration. After study and x-ray examination, the patient was operated upon by Dr. Arthur W. Elting; at operation, a large

ulcer in the prepyloric region of the stomach was found. Operation consisted of posterior gastro-enterostomy and appendectomy; recovery was uneventful. (Reported through the courtesy of Dr. A. W. Elting.)

CASE 2.—John T., male, age 37, entered the Memorial Hospital April 3, 1928, with a history of indigestion of 5 years' duration. Clinical and x-ray study revealed a duodenal ulcer. At that time operation was advised but refused by the patient; medical treatment was instituted with definite improvement. Six months later, on account of recurrence of symptoms, the patient submitted to posterior gastro-enterostomy; recovery was uneventful. (Reported through the courtesy of Dr. Edgar A. Vander Veer.)

CASE 3.—Harry T., male, age 27, entered the Memorial Hospital on the writer's service, Oct. 1, 1933, with a history of severe indigestion for 6 weeks. Three hours before admission he had been seized with severe "pains in the stomach" and vomiting. Operation disclosed a perforated ulcer, located on the anterior surface of the stomach about 2.5 cm. from the pylorus. The ulcer-bearing area was destroyed with the cautery and the defect closed with a double layer of sutures. Recovery was uneventful but recent check-up reveals that the patient is not symptom-free.

CASE 4.—Frank T., male, age 38, entered the Memorial Hospital on the writer's service on March 14, 1934. He was complaining of indigestion of 8 years' standing with frequent attacks of vomiting in the past 4 months. Radiographs showed marked pyloric obstruction apparently due to old ulceration. In a few days, posterior gastro-enterostomy and appendectomy were done; at operation a badly scarred pylorus was found buried in many adhesions. This patient developed a postoperative pneumonia and died on his sixth postoperative day.

CASE 5.—Helen T., single, female, age 23. She has suffered with stomach trouble for about 3 years. Recent radiographs revealed a duodenal ulcer. This patient is under medical treatment. (Reported through the courtesy of Dr. John F. Mosher, Coeymans, N. Y.)

302 STATE STREET

Dr. Lawson G. Lowrey, of the New York City Mental Hygiene Committee, thinks that the rise in new serious mental cases shows "really a remarkable advance in consciousness in regard to mental hygiene on the part of the general public rather than any recession in community sanity. Mental conditions are recognized more readily to-day and the attitude of the community has

changed noticeably in recent years from one of hopelessness to one of confidence. It is now a well-known fact that a relatively large number of persons can be improved, if not cured, when properly treated. This attitude has brought about an increased use of facilities for the diagnosis and treatment of mental conditions."

The Farmer and the Doctor

There is "one thing sacred," and that is 'freedom of action' It is Owen D Young speaking, and the man he pictures holding freedom sacred is the American farmer Mr Young was addressing an audience of farmers at the New York State Fair at Syracuse on September 4 The farmer 'accepts no man as his boss,' declared the author of the famous Young Plan 'He resents the discipline of the factory whistle," and, in fact, "all regimentation by anybody, for any purpose"

No one can read these splendid words without thinking of men of another calling who also resent regimentation The farmer aids Nature in her lavish reproduction of plant and animal life, the doctor aids Nature in the birth, preservation and perfection of human life, health and happiness Both are husbandmen, in different fields Both need that 'sacred freedom of action' to bring the best results It is precisely because both join hands with Nature at a vital point for a like vital purpose that both require freedom to apply their skill to the best advantage If you try to regiment them, to reduce

them to the level of 'hands' then you curb and clamp their usefulness, and must hamper their activity They must be individualists, they must demand freedom from coercion, they must resent the snooping and surveillance of petty bosses and managers or else be false to the task in the world which Nature has chosen for them and given into their care

It is not for himself that the doctor makes this demand for freedom, it is for his work Find the doctor who is pouring out his strength, his very life, in selfless toil to save the life and health of others, and there you will find the man who is fiercest in his demand that nobody shall interfere with his work If you wish to rouse his wrath to white heat, try to put him on an eight hour day or a twelve hour day, or try to regulate one iota of his unremitting toil The farmer, in the same mood, resents the daylight saving plan that would give him an extra hour of rest and recreation He prefers to regulate his daylight to suit himself It is in the very nature of the work of both farmer and doctor that they must be individualists

Again, both the farmer and the doctor have seen the rewards of their labor dwindling in recent years to a point where they are suffering real distress The legislative halls of the nation have reechoed with political pleas for the farmer till our government has set up vast loan funds to "assist" the farmer to mortgage his property and crops so deeply that when the depression is over he will be lucky if he has a clear title to his wheelbarrow The doctors, too, are to be taken care of by regimentation, they are to be assisted by enrolling them in panel systems such as prevail in European lands, where the plight of the harrassed, overworked, underpaid physician, bossed by lay managers, is certainly far from an improvement on American conditions

Well what is to be done, then, to keep this bad dream from coming true? What does Mr Young tell the farmer to do to preserve his sacred freedom of action? "If the farmer," says Mr Young, "is not to be ground into pieces between the upper

and the nether millstone, he must organize for his own protection and demand that his business, too, shall receive its just and fair reward. Prizing freedom as he does, loathing interference as he must, there may be no other course." Substitute the doctor for the farmer in this strong statement, and we come pretty near getting a working program to cure the economic ills of the medical profession.

What is preventing it? Again Mr. Young seems to put his unerring finger on the spot. The farmers are free men, he says, but "they are so free and so highly individualistic that it is difficult to unify them in an organization for their own protection, even in these days when organized minorities seem to be all-powerful." Transpose this picture to the medical profession, and do we not see the thousands of physicians who fail to unify themselves with the county, state and national medical organizations? They are the reserves who, if they would, could turn the tide of battle. Now is the time when they are needed.

Without the farmer and the doctor, the race would fall a prey to starvation and disease. With these two forced into poverty and dependence, the people will suffer by that much in nutrition and health. When the nation realizes this vital fact, it will rally to their support with sympathy and enthusiasm. The only forces that can prevent it are the forces of ignorance and prejudice, and they can be defeated by a vigorous campaign of education and enlightenment. Inaction is the Old Plan—it has failed. Action is the Young Plan—why not try it?

The Inter-State Post Graduate Medical Association of North America

Elsewhere in this issue will be found the full program of the coming International Assembly of this Association in Philadelphia in November next. While, ordinarily, space in the Journal cannot be devoted to scientific programs other than that of our own State Society, there are unique features in this assembly that may interest the entire membership.

The Association exercises no political or legislative duty, but aims to present the very latest and best in medical science. Diagnostic clinics, orations, symposia are offered by leading teachers and clinicians most of whom are members of faculties or connected with outstanding medical universities.

For the first time the annual assembly will be held east of the Alleghenies. The range of contributions covers all branches of medicine.

The Expert Medical Witness

This discussion is not concerned with the unscrupulous physician, if such exists, who is out to sell his opinions to the highest bidder. Such a character is of course beneath all consideration, and the only remark that can be made about him is that his duplicity can usually be made clear to a jury by an able and alert lawyer.

What is of more practical concern to the readers of these pages is the problem that faces the honest physician who is called to court to give expert medical testimony. He finds himself thrown at once into the middle of a bitter tangle of conflicting interests, he is harried by opposing counsel, thinly veiled slurs are cast on his knowledge and on the truth of his statements, in an effort to confuse him and destroy the force of his testimony, and in spite of all he can do he often leaves the witness stand with the feeling that the impression he has left behind is not of the best.

Not a little criticism, indeed, has been made of the doctor as an expert witness, and when physicians are called by both sides in a suit and present opposite conclusions on the same set of facts, the reflections tend to be a bit caustic. A leading jurist of Ohio recently remarked in an address before the Cincinnati Academy of Medicine that "unfortunately there is no type of witness who is so frequently looked upon with suspicion as the medical expert." Why is this the case? Why do juries tend to take a doctor's testimony with a grain of salt?

The answer is found by this magistrate,

Judge Benton S. Oppenheimer, in the perhaps natural desire of the physician to see his own opinions vindicated, or to see his friends or patients win their case. Judge Oppenheimer makes this diagnosis after years of experience with expert witnesses. Even the very manner and demeanor of the witness, he says, may reveal bias and partisanship, and make the opinions of the witness valueless to the jurors.

It is perfectly right, of course, for the doctor to have his preferences. He may feel that justice demands that one side shall win and the other lose. But the fact remains that the moment he reveals his bias on the stand, he injures the cause he seeks to aid. His value as an expert witness rests on his attitude of absolute and undeviating impartiality. Lose that, and his words go for nothing.

Let him show that his only desire is to aid the jurors to a just verdict, then his influence rises to the highest point. Let him answer all questions frankly and fairly, let him keep his calm and dignity, and he will carry the jury with him. He must avoid parading his accomplishments or displaying his learning, or he may seem ridiculous, which is fatal. If he does not know some point, let him say so. It strengthens belief in his other assertions, and gives the opposing counsel no chance to show up his ignorance later.

Then there is that bugaboo, the hypothetical question. Some one has said that hypothetical questions "are of great length and labyrinthian construction, the ambiguity of which is equaled only by the profound darkness shed by the answers thereto." Judge Oppenheimer makes the wise suggestion that when the doctor is aware that such a hypothetical question is to be flashed upon him, he will do well to acquire a copy of it before he enters the court, so that he may study it. The witness has the privilege, too, of asking that the question be made understandable, and he may ask the counsel if there are not additional facts that enter into the situation. Finally, if the question is too obscure, involved, or dubious, the witness may say that he is unable to answer, and the court will never force an answer to a question which is not understood.

The kernel of the judge's advice is that the physician on the witness stand preserve an unshaken dignity, frankness and impartiality. This will influence the jurors far more, he assures us, than any display of learning and ability. It is something that every physician can command, and something that will go far to re-establish respect for expert medical testimony.

Forgotten "Morro Castles"

The "Morro Castle" burns, with a loss of 135 lives, and the nation is shocked, acres of print discuss every detail, pages of pictures bring it to every eye. But suppose that four ships, one after another, in four successive weeks, burned with a loss of 135 lives each, and imagine then the sensation and outcry in the press and in every place where people meet. Well, even the toll of such a quadruple catastrophe would fall more than a hundred short of the number of victims of tuberculosis in New York State in June, 1934.

True, the death rate from pulmonary tuberculosis in the United States has dropped two thirds in 25 years and has fallen more than 50 per cent in this State and a world of credit is due the splendid workers who have brought it to pass, but the workers themselves would be the very first to say that the rate must be driven still lower. The well known special drive against tuberculosis in Syracuse proved that more effort will save even more lives. At more expense? Yes, but ridiculously less than the economic worth of the lives rescued.

All the wisdom of the Federal Government will be brought to bear on the "Morro Castle" holocaust to prevent any such marine disaster happening in the future, but the deaths from tuberculosis will keep on, week after week, month after month, year after year, because our federal, state, county, city, and town authorities do not seem to think it worth while to spend the money to save them. The Syracuse experiment showed that it is merely a matter of paying the bill for preventive measures and the death rate will drop. But because the victims are not burned to death on liners, few outside the medical

profession and the health service appear to care.

Let us look at another disease which we are finding preventable. More than 200 persons died of diphtheria and croup in New York City in 1932. Many of them might have been saved by preventive inoculation. Here is a disaster 50 per cent greater than the holocaust of the "Morro Castle." The lives of the 200 diphtheria victims were just as valuable as the lives of the 135 ship passengers. In the same year in New York City 3397 died of pulmonary tuberculosis, and thousands more of other diseases which no doubt might have been arrested if taken in time. Of all the 74,319 deaths in the city in that year (over 200 a day) only 120 are attributed to old age.

Here again, the morbidity and mortality of diphtheria, like tuberculosis, have been marvelously reduced in recent years, but the doctors and health workers are the sort of people who are never satisfied. In this state the campaign against diphtheria that started in 1925 cut the morbidity from 116 cases to only 20 per 100,000 population, and the mortality from 8.6 to a mere 1.1. The weapon was immunization, the fighting man was the family doctor. It

stands to reason that if these rates have been cut so splendidly, they can be reduced still further, and, as a matter of fact, the State Department of Health has a vigorous campaign on for that very purpose at this moment. Again, extra effort with but trifling addition to expense is the answer.

If we imagine human society as embarked on a great liner, threatened by flames which snatch their victims by the score, the hundred, the thousand, and if we imagine the doctors as the life-saving crew fighting the fire and pulling the victims from its grasp, then what shall we say of the indifference of authorities who fail to give the physicians their full co-operation, and what shall we say of a Congress at Washington which permits charlatans to engage in what is equal to spraying gasoline on the fire or throwing life-preservers of lead to the drowning? The spectacle of the Copeland Bill being strangled to death in the last Congress is a case in point.

It is splendid to be excited over the "Morro Castle" tragedy. It will be still finer when we grow excited over our other tragedies, too.

COMMITTEE ON LEGISLATION

FINAL BULLETIN OF SPECIAL LEGISLATIVE SESSION

September 22, 1934

The thirty-day period allowed the Governor for action upon bills passed by the Legislature at its special session has elapsed and we are in a position to give you the final report. There follows a statement of the action taken on the bills in which we were interested:

SENATE INT. 8—Ross (same as ASSEMBLY INT. 9—Banfield), appropriating \$1,500,000 for payment of indemnity for suppression and eradication of bovine tuberculosis to supplement similar payments to be made by Federal Government. Chapter No. 916.

SENATE INT. 15—Lord, appropriating \$1,500,000 for paying indemnities on account of bovine tuberculosis suppression. Died in Senate Finance Committee.

SENATE INT. 17—McNaboe, levying 2 per cent retail sales tax. Died in Senate Taxation Committee.

SENATE INT. 24—Fearon, provides for the supplying of free milk to undernourished babies and nursing mothers and for direct purchase of milk from dealers and distribution by welfare commissioners, local relief bureaus or other agency approved by the Temporary Emergency Relief Administration. Chapter No. 874.

SENATE INT. 71—Esquirol (same as ASSEMBLY INT. 45—Stewart), amending Education Law by providing a person to qualify as a registered nurse must be a citizen of the United States or shall have made application to become a citizen on or before September 1, 1935. Chapter No. 855.

ASSEMBLY INT. 5—Cornaire, appropriating \$1,500,000 to pay indemnities on account of bovine tuberculosis suppression. Vetoed by Governor.

ASSEMBLY INT. 93—Murphy, adding new section to the Education Law prohibiting

importation of a dog into State for scientific experiment, test or investigation involving laceration or incision or mutilation of, or the causing of pain or suffering to such dog. Died in the Assembly Education Committee.

We are in the midst of a campaign period and it is well to remember that this year we elect a Governor, Senators and Assemblymen. It is exceedingly important, therefore, that every chairman and members of his committee should make it a point of interviewing the various candidates to make certain that they are familiar with the Medical Society's point of view on medical questions so that full support may be given the proper candidates. With the objective of providing the citizens of the State with the best medical care and public health service obtainable, your committee has annually urged the county chairmen to interest themselves in securing the election of suitable men to the Legislature. In this period of social unrest this annual request is more important than ever. The Legislative Committee of the Illinois State Medical Society is making a similar request of its county committees and this appeal is so forceful that we are taking the liberty of including some excerpts in our communication. We should like to reproduce the entire letter.

In their home districts where votes are cast, politicians are superlative listeners, the best and most sensitive in the world. For this reason physicians are in a peculiarly strategic position to exercise an important and usually a determining influence in the character and trend of legislation, particularly on matters relating to medicine. As a political force, the organized medical profession does not claim great power and could not very well be otherwise. As individuals the physicians can and should be powerful factors in those political matters which influence the practice of medicine from the standpoint of patient, public, and doctor.

"In order to exercise his right of franchise intelligently and to perform his duty to himself and community every physician in Illinois should make it a point to meet and get acquainted with every candidate for the State and National legislatures. He should communicate to these candidates his opinions con-

cerning medical matters that are apt to be up for legislative consideration. A ten-minute chat with a candidate prior to election and under favorable circumstances is worth more in moulding his attitude on legislative matters than a dozen delegations of lobbyists after the General Assembly convenes.

'Physicians are intimately acquainted with many people. This gives to them a particularly advantageous approach to political leaders. By using this advantage the physician can obtain a sympathetic hearing that will have a powerful influence over the crystallization of thought in the minds of legislators.

"Your Legislative Committee wishes to urge upon you the duty and responsibility that is yours in respect to political matters. How or for whom you vote is relatively unimportant so far as party alignment is concerned. Your political faith, so far as parties are concerned, is a matter of indifference to your Committee. That you make contact with candidates and express your opinions on medical problems is of the greatest importance, however.

"Moulding legislative thought by contact with candidates is an opportunity, a privilege, and a duty of every physician. In this way he can do important constructive service in building the governmental structure on a sane, firm foundation. Criticizing politicians and bewailing government activity after new laws have been enacted is the poorest way known to correct undesirable trends much less to prevent evil legislation.

"Physicians as well as the public are aware of the many articles appearing in the daily press and current periodicals advocating the subsidizing of the medical profession, one of the most recent being 'A Plea for Socialized Medicine,' in the September issue of 'Mercury,' written by George W. Aspinwall, which the editor says is the pen name of an eminent New York physician. Silence and apathy on the part of the individual physician to such propaganda will be construed by the lawmakers as an approval of the medical profession."

HARRY ARANOW, Chairman,
COMMITTEE ON LEGISLATION

ENDORISING VOLUNTARY HEALTH INSURANCE

An interesting point is made by the *New York Medical Week* in its comment on the endorsement of voluntary health insurance by the American College of Surgeons. There is no evidence, it observes, that the vote of the delegates represented the opinion of the membership, for the fellows were not asked to voice their opinion. It is so important that we should know by what

authority, it asks, did the Board of Regents, constituted for a totally different purpose, depart from their fixed road and take the path which might have serious consequences for the Fellows who elected them no less than for the profession as a whole? Even if the unanimous opinion of the Fellowship supported the Regents' stand, however, they would still represent only a minority of the physicians of the country.

Medicolegal

LORENZ J. BROSNAN, ESQ.
Counsel, Medical Society of the State of New York

Illegal and Fraudulent Practice of Medicine

Recently a very interesting series of cases came before the Courts of one of the Western States involving a certain man who engaged in a type of medical quackery, which merit discussion in these columns.

The first of these cases was brought against the offender, H., to recover the sum of \$10,000 as damages, by an elderly woman, apparently a plain country woman of limited intelligence, upon charges that she had been the victim of a scheme to cheat and defraud her of various sums of money. She obtained a judgment against H., amounting to the sum demanded.

The facts that developed upon the trial were substantially as follows:

The plaintiff, G., was afflicted with a cancerous growth upon her left breast which, according to medical testimony, was at the time curable and consulted the defendant at his office. The plaintiff had heard that he had held himself out for a long time as a physician and surgeon able to treat and cure cancers. He examined her and made a diagnosis of her case by rubbing his fingers along her left arm. He told her that she did not have cancer for she did not have any "virus" in her blood. He told her, however, that she was suffering from kidney and a growth which would develop into cancer if left alone without treatment. He recommended to her a certain medicine which he called "oil of radium." He sold her two bottles of that medicine for \$125.00, telling her that the two bottles contained sufficient medicine to cure her. She was instructed to rub some of the contents of one bottle on the surface of the growth every day and to take the other bottle internally. She used the medicine as directed and upon rubbing it upon the cancerous growth, according to her testimony, it gave her pain and caused a bloody substance to exude from the growth. She returned to him after six weeks and he examined and told her she was improving. She again returned to H. three weeks later and at that time he again examined her by the method of running his fingers along her arm and exclaimed to her, "My God,

woman! What have you been doing? There is virus in your blood now." He sold her more of his "oil of radium" (which he told her was of a "higher specific") for \$45.00, which, he said, would cure the condition that she had developed. Some time later she again returned and he refused to examine her, but his secretary sold her more medicine. Still later she returned and H. examined her again and told her that she must keep on taking medicine for the "virus" in the blood and obtained from her a check for \$45.00 for another bottle of his "higher specific." At that time her husband became suspicious and stopped payment on the check and H. came to the plaintiff's home in an attempt to collect the \$45.00. The plaintiff lost faith in H. and his purported cures and sought medical advice and learned that the medicine that she had taken had done her no good and that while she was under the care of H., her condition, which actually was cancer, had become inoperable.

The testimony upon the trial, in addition to bringing out the above facts, showed clearly that the defendant went under the name of "Doctor," although he was not a physician licensed under the laws of the state. Respectable medical testimony was introduced on behalf of the plaintiff which showed that the plaintiff having relied upon the treatment prescribed by the defendant had neglected proper medical attention for her case and that her disease had grown worse until it was too late to administer any helpful treatment to her. It was established upon the trial that the preparation which the defendant called "oil of radium" was unknown to medical science.

The defendant attempted to claim that the treatment prescribed by him was a proper one and that the patient had sustained unsatisfactory results because she had not followed his directions.

The case was sent to the jury upon the theory of fraud and the plaintiff was awarded \$7500.00 as actual damages and \$2500.00 for punitive damages.

An appeal was taken and one of the chief contentions of H. was that the vic-

tim was entitled only to collect from him the amounts she had paid him for the medicines. The court, however, ruled that he had been guilty of a misdemeanor in the case, having undertaken to practice medicine without a license, and he should be liable for the damage that he had caused. The court in the opinion said:

"The defendant below manually, by feeling of plaintiff's arm and examining her, diagnosed her disease and prescribed a treatment therefor. He is therefore liable in civil damages for the detriment suffered by reason of his having violated an express statute. The wrong complained of is the violation of an express statute in the pretended practice of medicine. The damage claimed is an injury resulting by reason of preventing the plaintiff from securing proper medical attention. The question is, then, as to the breach of the statute, was such damage the natural, probable and approximate result of the acts of the defendant? The purpose of the statute was to prevent unskilled persons from preying upon an unsuspecting public and to eliminate the detriment that might be caused by malpractice. Hence, a person violating the statute does so with knowledge that one of its natural and probable consequences may be detriment caused both in pain and suffering and in neglect of proper medical attention."

Thereafter a similar suit came before the Courts in which H was held responsible for the sum of \$2000 00 damages. In that case the facts were as follows:

A certain S B had been suffering from some ailment for several months and consulted H at his offices with respect to her condition. She was advised by H and his wife of the ability of Dr H and of the wonderful and extraordinary remedies that he dispensed for the purpose of treating all sorts of diseases. H made a diagnosis of her case and advised her that she was suffering from weak heart, weak lungs, weak kidneys and tuberculosis of bone tissue. He told her that she was dying by inches and that unless she took immediate treatment in the form which he directed her life would be very short. She agreed to undergo his form of treatment and purchased from him, at a cost of \$125 00, some of his "oil of radium." He told her at the time that the said medicine was a rare one and could not be procured in America except from him. She took the medicine as directed and,

according to her testimony upon the trial, it caused a burning sensation in her stomach and caused her a great amount of pain and suffering. After finding that the treatment directed by Dr H was doing her absolutely no good, she sought medical attention and learned that she was suffering from chronic appendicitis. She underwent an operation for that condition and after that had been performed she regained her health.

The patient instituted an action against H, similar to the one previously mentioned, to recover damages for his false representations. Again the defendant sought to contend that the only action which the plaintiff might have against him was to recover the sum of \$125 00, the amount that had been paid to him by the patient, and again that contention was ruled out. Upon the trial the defendant sought to offer evidence that he had treated and cured other patients by the use of his extraordinary remedy, but the court excluded the said evidence and upon appeal the said ruling of the Trial Court was supported. The jury's award in favor of the plaintiff of \$2000 00 was not disturbed by the Appellate Court.

In a third case against H he was held responsible for \$3000 00 damages to another gullible woman who had purchased and used his "oil of radium" as a cancer cure, upon his representations that he was a licensed physician able to cure any and all human diseases.

After these persons and undoubtedly many others had received treatment at the hands of H, criminal charges of practicing medicine without a license were brought against him. The State's evidence was chiefly that of a patient who was examined by H and was told she had a tumor and was on the verge of "TB." He had sold her two bottles of his "oil of radium" for \$125 00 to be used one for external and one for internal use.

Upon the trial H put in no testimony, and failed to take the stand in his behalf. His chief defense was that he had made no charge for advice or examination but had only charged a fee in connection with the sale of the medicine. The Appellate Court disposed of his said contention with the following language:

"He argues that it is no violation of law for any person to sell medicine in his home, and that the evidence does not sustain the charge. This contention cannot be sustained. It is evident that the physical examination, the pretended diagnosis,

and the imposing on the credulity of the patient by the sale of a worthless preparation for \$125.00 constitutes but a single transaction, and while it is probably true that at the time the defendant informed his patient he was charging the \$125.00 for the two bottles of drugs and not for the examination and diagnosis, this does not alter the situation. The entire transaction is a practice of medicine within the definition of the Medical Practice Act.

The fact that the defendant informed his patient at the time that this charge was for the pretended medicine is plainly but a subterfuge to avoid the provisions of the law."

The consistent stand of the Appellate Courts in each of these cases in refusing to give any sympathy to the various contentions of H. in his attempts to avoid the just consequences of the obvious quackery he had engaged in, is admirable.

INTERNATIONAL ASSEMBLY

of the

INTER-STATE POSTGRADUATE MEDICAL ASSOCIATION

of

NORTH AMERICA

As previously announced in the JOURNAL, the Assembly of this organization will be held in Philadelphia, Pa., on November 5, 6, 7, 8, and 9, 1934. Through the combined efforts of the medical profession of Philadelphia, a stage is being set for a remarkable Assembly, which is bound to contribute a great deal of valuable scientific and clinical knowledge to the profession of North America. The program follows in detail.

PROGRAM

Pre-Assembly Clinics, November 3rd;
Post-Assembly Clinics, November 10th;
Philadelphia Hospitals

Monday, November 5th

8:00 A. M.

Diagnostic Clinic: "Peptic Ulcer."

Dr. Edward J. Klopp, Professor of Surgery,
Jefferson Medical College of Philadelphia,
Philadelphia, Pa.

Diagnostic Clinic: "Tuberculosis of the Genito-Urinary Tract."

Dr. Hugh H. Young, Professor of Urology,
Johns Hopkins University School of Medicine,
and Director of the Brady Urological
Institute, Johns Hopkins Hospital, Baltimore,
Md.

Diagnostic Clinic: "Diagnosis and Treatment of Myxedema."

Dr. Cyrus C. Sturgis, Professor of Medicine,
University of Michigan Medical School, and
Director of the Thomas Henry Simpson
Memorial Institute for Medical Research,
Ann Arbor, Michigan.

Intermission for Review of Exhibits

Diagnostic Clinic: "Complications of Pregnancy."

Dr. John R. Fraser, Professor of Obstetrics
and Gynecology, McGill University Faculty
of Medicine, Montreal, Canada.

Diagnostic Clinic: "Hoarseness—Differential Diagnosis of the Manifold Diseases Accompanied by this Symptom."

(A) Chalk Demonstration of Pathologic Mechanism of Hoarseness.

Dr. Chevalier Jackson, Professor of Bronchoscopy and Esophagoscopy, Temple University School of Medicine, Philadelphia, Pa.

(B) Lantern Slide Demonstration of Clinical Cases.

Dr. Chevalier L. Jackson, Professor of Clinical Bronchoscopy and Esophagoscopy, Temple University School of Medicine, Philadelphia, Pa.

Noon Intermission

1:00 P. M.

Diagnostic Clinic: "Varieties of Goiter and Their Management."

Dr. Frank H. Lahey, Director of Surgery in the Lahey Clinic; Surgeon to the New England Baptist Hospital and New England Deaconess Hospital, Boston, Mass.

Address: "The Treatment of Chronic Constipation."

Dr. Frederick J. Kalteyer, Clinical Professor of Medicine, Jefferson Medical College of Philadelphia, Philadelphia, Pa.

Address: "Postoperative Complications."

Dr. Elliott C. Cutler, Moseley Professor of Surgery, Harvard University Medical School, Boston, Mass.

Intermission for Review of Exhibits

Address: "The X-ray Diagnosis of Various Pathological Conditions of the Small Intestine with Special Reference to Postoperative and Post-inflammatory Conditions."

Dr. James T. Case, Professor of Roentgenology, Northwestern University Medical School, Chicago, Illinois.

Address: "The Value of X-ray Therapy in Acute and Chronic Infection."

Dr. Willis F. Manges, Professor of Roentgenology, Jefferson Medical College of Philadelphia, Philadelphia, Pa.

Address "Concerning the Recognition of Certain Symptoms and External Ocular Signs Referable to General Diseases"

Dr. Thomas B. Holloway, Professor of Ophthalmology, School of Medicine, University of Pennsylvania, Philadelphia, Pa
Dinner Intermission

7 00 P M.

Address "The Surgical Treatment of Tumors of the Suprarenal Gland"

Dr. Waltman Waters, Associate Professor of Surgery, University of Minnesota, Graduate School of Medicine, Mayo Clinic, Rochester, Minnesota

Address "New Method of Ventriculography through the Vault of the Orbit"

"Final Recovery of the Facial Spasm after Plastic Reduction of Nervous Fibers"

Dr. A. M. Dogliotti, Professor of Surgical Diagnostic, Royal University of Torino Vice-President of the International Society of Anesthesia, Member of the Reale Accademia di Medicina, Torino, Italy

Address "Qualitative Changes in the Neutrophilic Leucocytes," Illustrated with Natural Color Photomicrographs (10 min)

Dr. Russell L. Haden, Chief of the Medical Division, Cleveland Clinic, Cleveland, Ohio

Address "Certain Problems Presented by the Adolescent Period"

Dr. William Palmer Lucas, Clinical Professor of Pediatrics, University of California Medical School, San Francisco, California

Address "The Significance of Menopausal Bleeding"

Dr. Floyd E. Keene, William Goodell Professor of Gynecology, University of Pennsylvania School of Medicine, Philadelphia, Pa

Tuesday, November 6th

8 00 A M

Diagnostic Clinic "Chronic Appendicitis and Diseases which Stimulate It"

Dr. George P. Muller, Professor of Clinical Surgery, University of Pennsylvania Graduate School of Medicine, Surgeon to the Lankenau and Misericordia Hospitals, Philadelphia, Pa.

Diagnostic Clinic "The Simulation of Chronic Glomerulo-Nephritis by Conditions not Primarily Renal"

Dr. O. H. Perry Pepper, Professor of Medicine University of Pennsylvania School of Medicine, Philadelphia, Pa

Diagnostic Clinic "Diagnosis and Treatment of Urinary Calculi"

Dr. William E. Lower, Cleveland Clinic Cleveland, Ohio

Intermission for Review of Exhibits

Diagnostic Clinic and Address "The Basic Nature of Chronic Arthritis and the Principles underlying Treatment"

Dr. Robert B. Osgood, John Ball and Buckminster Brown Professor (Emeritus) of Orthopaedic Surgery, Harvard University Medical School, Boston, Mass., and

Dr. Ralph Pemberton, Professor of Medi-

cine, University of Pennsylvania Graduate School of Medicine, Philadelphia, Pa
Noon Intermission

1 00 P M.

Diagnostic Clinic "Postoperative Abdominal Fistula"

Dr. John F. Erdmann, Attending Surgeon to the New York Post Graduate Hospital and Medical School, New York, N Y

Address "Recent Advances in the Treatment of Urinary Infection"

Dr. William C. Quimby, Clinical Professor of Genito Urinary Surgery, Harvard University Medical School, Boston, Mass

Address "Chronic Duodenojejunal Angle Ileus Simulating Gastric Crises of Tabes Dorsalis"

Dr. Ralph C. Brown, Clinical Professor of Medicine, Rush Medical College, University of Chicago Chicago Illinois

Intermission for Review of Exhibits

Address "The Treatment of Myomata—Operation and Irradiation"

Professor Dr. Har-
of Obstetrics and
sity, Director of
Hospital, Berne, Switzerland

Address "The Management of Common Colds"

Dr. Perry G. Goldsmith, Professor of Otolaryngology, University of Toronto Faculty of Medicine, Chief Surgeon Department of Otolaryngology, Toronto General Hospital, Toronto, Can

Address "Present Status of Immunization against Communicable Diseases"

Dr. John A. Kolmer, Professor of Medicine, Temple University School of Medicine and Director of the Research Institute of Cutaneous Medicine, Philadelphia, Pa
Dinner Intermission

7 00 P M.

Address "Indications for and Type of Surgery in the Treatment of Duodenal Ulcer"

Dr. Roscoe R. Graham, Assistant Professor of Surgery, University of Toronto Faculty of Medicine, Senior Surgeon Toronto General Hospital, Toronto, Canada

Address "Clinical Aspects of the Various Important Types of Constitution"

Dr. Lewellyn F. Barker, Professor Emeritus of Medicine Johns Hopkins University School of Medicine, Visiting Physician, Johns Hopkins Hospital, Baltimore, Md

Address "Technique of Pneumonectomy and Lobectomy" (10 min)

Dr. William F. Rienhoff, Jr, Instructor in Surgical Anatomy, and Associate in Surgery, Johns Hopkins University School of Medicine, Baltimore Md

Address "Diagnosis of Pancreatic Cysts"

Dr. Allen O. Whipple, Professor of Surgery, Columbia University College of Physicians and Surgeons, New York, N Y

Address "Vascular Crises"

Dr. David Riesman, Professor Emeritus of Clinical Medicine, and Professor of the History of Medicine University of Pennsylvania School of Medicine, Philadelphia Pa

Wednesday, November 7th

8:00 A. M.

Diagnostic Clinic: "Differential Diagnosis of Syphilitic and Non-Syphilitic Eruptions."
Dr. Frank C. Knowles, Professor of Dermatology, Jefferson Medical College of Philadelphia, Philadelphia, Pa.

Diagnostic Clinic: "Pain."

Dr. John M. T. Finney, Professor of Clinical Surgery, Johns Hopkins University School of Medicine; President of Inter-State Post Graduate Medical Association of North America, Baltimore, Md.

Diagnostic Clinic: "What Constitutes a Good History."

Dr. William D. Haggard, Professor of Clinical Surgery, Vanderbilt University School of Medicine; President, American College of Surgeons, Nashville, Tenn.

Intermission for Review of Exhibits

Diagnostic Clinic: "The Significance of Jaundice."

Dr. Henry A. Christian, Hersey Professor of the Theory and Practice of Physic, Harvard University Medical School, and Physician-in-Chief, Peter Bent Brigham Hospital, Boston, Mass.

Diagnostic Clinic: "Diagnosis and Treatment of Brain Tumors."

Dr. Walter E. Dandy, Adjunct Professor of Neurological Surgery, Johns Hopkins University School of Medicine, Baltimore, Md.

Noon Intermission

1:00 P. M.

Address: "The Surgery of Amelioration for Intractable Urological Lesions."

Dr. Joseph F. McCarthy, Professor of Clinical Urology, Executive Officer of Department of Urology, New York Post Graduate Medical School, Columbia University, New York, N. Y.

Address:

Dr. Paul Strassmann, Professor of Obstetrics and Gynecology, Medical Department, University of Berlin, Berlin, Germany.

Address: "Pregnancy Associated with Diabetes."
"The Use of Cholesterol in the Treatment of Diabetes."

Dr. Elliott P. Joslin, Clinical Professor of Medicine, Harvard University Medical School, Boston, Mass.

Address:

Dr. William J. Mayo, Chief of Staff, Mayo Clinic, Rochester, Minn.

Intermission for Review of Exhibits

Address: "Problems Relating to Peritonitis."

Dr. Vernon C. David, Clinical Professor of Surgery, Rush Medical College, University of Chicago, Chicago, Illinois.

Address: "Chronic and Recurring Diarrheas."

Dr. Robert G. Torrey, Professor of Medicine, Woman's Medical College of Pennsylvania, and Physician to the Philadelphia General Hospital, Philadelphia, Pa.

Address: "Fundamental Physiological Concepts Differentiating Arterial from Arteriovenous Lesions and Their Importance in Relation to Surgical Therapy." Clinical and Experimental Studies.

Dr. Emile F. Holman, Professor of Surgery, Stanford University School of Medicine, San Francisco, California.

Address: "Streptococcus Infections."

Dr. Warfield T. Longcope, Professor of Medicine, Johns Hopkins University School of Medicine, Baltimore, Md.

Dinner Intermission

CONVENTION DINNER

Addresses by Distinguished Guests

Thursday, November 8th

8:00 A. M.

Diagnostic Clinic: "Functional Disorders of the Gastro-Intestinal Tract."

Dr. Alfred Stengel, Professor of Medicine, University of Pennsylvania School of Medicine, Philadelphia, Pa.

Diagnostic Clinic: "Back Injuries."

Dr. John J. Moorhead, Clinical Professor of Surgery, New York Post Graduate Medical School, New York, N. Y.

Diagnostic Clinic: "Malignant Hypertension, Manifestations and Treatment."

Dr. Campbell P. Howard, Professor of Medicine, McGill University Faculty of Medicine, Physician to the Montreal General Hospital, Montreal, Canada.

Intermission for Review of Exhibits

Diagnostic Clinic: "Benign Tumors of the Breast."

Dr. Dean D. Lewis, Professor of Surgery, Johns Hopkins University School of Medicine, Baltimore, Md.

Diagnostic Clinic: "Pain in the Chest."

Dr. James H. Means, Jackson Professor of Clinical Medicine, Harvard University Medical School, and Chief of the Medical Services, Massachusetts General Hospital, Boston, Mass.

Noon Intermission

1:00 P. M.

Diagnostic Clinic: "Differential Diagnosis of Border Line Cases."

Dr. Hugh Cabot, Professor of Surgery, University of Minnesota, Graduate School of Medicine, and Consulting Surgeon at the Mayo Clinic, Rochester, Minnesota.

Address: "Gynecological and Obstetrical Applications of Endocrinology."

Dr. Emil Novak, Associate in Gynecology, Johns Hopkins University School of Medicine, Baltimore, Md.

Address: "Litigation of the Splenic Artery in Some Splenomegalic Affections."

Dr. Roberto Alessandri, Professor of Surgery, Royal University of Rome, Rome, Italy.

Intermission for Review of Exhibits

Address: "Diverticulitis and Carcinoma of the Colon with Special Reference to the Differential Diagnosis."

Dr. Ross Golden, Associate Professor of

Medicine, Columbia University College of Physicians and Surgeons, Attending Physician Roentgen Ray Department, Presbyterian Hospital, New York, N Y

Address 'The Treatment of Acute and Chronic Mastoiditis'

Dr. Fielding O Lewis, Professor of Laryngology, Jefferson Medical College of Philadelphia, Philadelphia, Pa

Address 'The Diagnosis and Management of Diseases of the Biliary Tract'

Dr W. Wayne Babcock, Professor of Surgery, Temple University School of Medicine Surgeon Philadelphia General Hospital, Philadelphia, Pa

Dinner Intermission

7 00 P M

Address 'The Surgical Aspects of Essential Hypertension'

Dr George J Heuer, Professor of Surgery, Cornell University Medical College, New York, N Y

and

Dr I H Page, Rockefeller Institute for Medical Research, New York N Y

Address 'Some Aspects of the Etiology, Diagnosis and Treatment of Anemia'

Dr George R Minot, Professor of Medicine, Harvard University Medical School, Director, Thorndike Memorial Laboratory Visiting Physician, Boston City Hospital, Boston, Mass

Address 'Certain Aspects of Surgery of the Large Intestine' (10 min)

Dr Richard B Cattell, Lahey Clinic, Boston, Mass

Address 'The Relation of the Endocrines to the Psychoses'

Dr Louis J. Karnosh, Assistant Clinical Professor of Nervous Diseases, Western Reserve University School of Medicine, Cleveland, Ohio

Address 'Intracranial Injuries of the New Born from the Standpoint of the General Practitioner' (Moving Picture Demonstration)

Dr P. Brooke Bland, Professor of Obstetrics, Jefferson Medical College of Philadelphia, Philadelphia Pa

Friday, November 9th

8 00 A M

Diagnostic Clinic 'Polomyelitis'

Dr John Claxton Gittings, William H Bennett, Professor of Pediatrics, University of Pennsylvania School of Medicine, Philadelphia, Pa

Diagnostic Clinic 'The Diagnosis of Primary Pituitary and Parapituitary Lesions'

Dr Charles H Frazier, John Rhea Barton Professor of Surgery University of Pennsylvania School of Medicine, Philadelphia, Pa

Diagnostic Clinic 'Primary Carcinoma of the Lung'

Dr. Evarts A Graham, Bryby Professor of Surgery, Washington University School of Medicine, St Louis, Mo

Intermission for Review of Exhibits

Diagnostic Clinic 'Polyglandular Disease'

Dr. George Crile, Cleveland Clinic, Cleveland Ohio

Diagnostic Clinic 'Pernicious Anemia and Leukemia'

Dr Harlow Brooks, Emeritus Professor of Clinical Medicine, New York University and Bellevue Hospital Medical College, New York, N Y

Noon Intermission

1 00 P M

Diagnostic Clinic 'Differential Diagnosis of Tuberculous and Non Tuberculous Infection'

Dr. Charles R Austrian, Associate Professor of Medicine Johns Hopkins University School of Medicine Baltimore, Md

Diagnostic Clinic 'The Curability of Carcinoma'

Dr E Starr Judd, Professor of Surgery, University of Minnesota Graduate School of Medicine, Mayo Clinic, Rochester, Minn

Address 'Recent Advances in our Knowledge of the Thymus and Pinea Glands'

Dr Leonard G Rowntree, Director of the Philadelphia Institute for Medical Research, Clinician to the Philadelphia General Hospital, Philadelphia, Pa

Address

Dr Charles H Mayo, Professor of Surgery, University of Minnesota Medical School, and University of Minnesota Graduate School of Medicine, (Mayo Foundation), Rochester, Minn

Intermission for Review of Exhibits

Address 'The Treatment of Hirschsprung's Disease'

Dr Fred W Rankin, Lexington, Kentucky

Address 'The Present Status of Surgery of the Sympathetic Nervous System'

Dr Alfred W Adson, Professor of Neurosurgery University of Minnesota Graduate School of Medicine Chief of the Neurological Department, Mayo Clinic Rochester, Minn

Address 'Functional Nervous Disorders in Children'

Dr Edward L Bauer, Professor of Diseases of Children, Jefferson Medical College of Philadelphia, Pediatricist to the Jefferson Hospital, Philadelphia, Pa

TENTATIVE FOREIGN ACCEPTANCES

Dr Ferdinand Sauerbruch, Prof and Head of the Department of Surgery, University of Berlin, Berlin Germany
Sir Harold Gillies, London, England

Books

BOOKS REVIEWED

Red Blood Cell Diameters.—By Cecil Price-Jones, M.B. Octavo of 82 pages. New York, Oxford University Press, 1933. Cloth, \$3.50.

This concise book of 80 pages deals with the history of red blood-cell mensuration and the present-day methods of measuring the diameters of the erythrocytes. It contains many interesting charts and graphs of the size of red blood-cell diameters in health and disease. The book is of especial value to technicians and those interested in hematology.

REGINALD J. BLABER

The Harvey Lectures.—Delivered Under the Auspices of the Harvey Society of New York, 1932-1933. Series 28. Julius Bauer, M.D., L. O. Kunkel, M.D., and others. Octavo of 233 pages, illustrated. Baltimore, Williams & Wilkins Company, 1934. Cloth, \$4.00.

The 1932-1933 series continues to maintain its traditional and high standard of lectures with the following: **Constitutional Principle in Clinical Medicine**, by Julius Bauer: A dissertation on genetics in constitution and its role in disease. There are interesting remarks on genotypical chromosomal relationships in a large series of hereditary diseases.

Diseases of Vegetables and Man, by L. O. Kunkel: A description of various virus diseases which occur in both plant and animal life treating particularly with the similarity of their biological behavior.

Nature of Menstrual Cycle, by G. W. Corner: A very clear presentation of ovulation in its relation to menstruation which includes much of the author's own experiments in monkeys.

Dyspituitarism, by Harvey Cushing: The second lecture on the same subject after a further experience over a period of 24 years. This lecture deals largely with the functioning adenomatous tumor of the anterior pituitary.

Oxidation of Hemoglobin and other Respiratory Pigments, by James B. Conant: Concerned with the molecular structure of hemoglobin and hemocyanin, their physicochemical behavior, and their role in oxygen transport.

Other lectures include: **Contributions of Chemistry to Knowledge of Immune Processes**, by Michael Heidelberger; **Liver Function in Relation to Fat Metabolism**, by J. C. Drummond; **Transmission of Nervous Impulse**, by Otto Loewi.

WILLIAM S. COLLENS

Localization of Function in the Cerebral Cortex.—An Investigation of the Most Recent Advances. Proceedings of the Association for Research in Nervous and Mental Disease. Vol. XIII, 1932. Octavo of 667 pages, illustrated. Baltimore, The Williams & Wilkins Company, 1934. Cloth, \$8.00.

This volume covers the anatomical, physiological, and clinical aspects of this complicated topic. In the anatomical section Dr. Tilney deals mainly with the phylogeny and ontogeny of the cerebral cortex. In the physiological section there are presented the results of a study made by Drs. J. F. Fulton and Margaret A. Kennard on the flaccid and spastic paralyses produced in primates by lesions of the cerebral cortex. The final section of the book will appeal most to neurologists by reason of the clinical value of the studies made. Frazer and Rowe report on 51 tumors of the temporal lobes. A carefully studied case of bilateral lobectomy of the frontal lobes is reported by Dandy. In a similar manner, Drs. Penfield and Jos. Evans report on their case of lobectomies. Various lobes were removed with surprisingly little functional disturbance. In a study of functional disturbances caused by lesions of the post-Rolandic area, Winkelman and Silverstein find, in addition to the usual sensory disturbances, atrophy of the muscles in the contralateral limbs and trophic changes. For lack of space one must of necessity omit the consideration of other very interesting papers. Altogether, this volume is packed with interesting matter, presented by masters in their respective fields.

JOSEPH SMITH

Aids to Pathological Technique.—By David H. Haler. 16mo. of 187 pages. Baltimore, William Wood & Company, 1933. Cloth, \$1.50.

This pocket size volume is a combination of laboratory manual and compend for students preparing for examination. The author presents laboratory methods in bacteriology, hematology, cytology and parasitology, biochemistry, the preparation of culture media, and formulae for solutions and stains. But one method is given for each test and there is no theoretical discussion

except to give the principles underlying some of the tests. There are a few pen and ink illustrations.

The author is an English pathologist and some of his methods, especially the technic of the Wasserman test and some of the methods in hematology, are different from American methods. However, this is a very practical little handbook.

E. B. SMITH

Les Artères Coronaires du Cœur Chez L'Homme.—By Docteur Aime Mouchet. Second Edition. Quarto of 63 pages and 18 plates. Paris, Norbert Maloine, 1933.

Professor Mouchet has written an exceedingly interesting monograph dealing with the anatomy of the coronary arteries and their anastomoses. He has employed three important methods of study: (1) systematic dissection and mensuration of the coronaries in 200 hearts, (2) radiographic study after injection in 300 hearts, (3) perfusion experiments to study anastomoses in 100 specimens.

He gives a clear and authoritative description of the anatomical distribution of both coronaries, describing in each instance the commonest arrangement and three other less common distributions. His description of the blood supply of the auricles and of the conduction system is especially good.

As to the question of anastomoses between right and left coronary arteries, he brings clear evidence to show that such anastomoses do exist, that they are absent in some instances, rarely voluminous, and that they are usually represented by very fine arterioles. The question of the value of these anastomoses he leaves to the physiologist.

The last half of the volume is made up of seventeen beautiful reproductions of radiographs of injected coronaries. The possession of these alone makes the work desirable.

EDWIN P. MAYNARD, JR.

Demonstrations of Physical Signs in Clinical Surgery.—By Hamilton Bailey, F.R.C.S. Fourth Edition. Octavo of 287 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$6.50.

This is the latest revision of a most interesting work well illustrated by actual bedside examination technic. The illustrations are worth careful study, especially when described by one associated in the teaching of physical examination to the student body at the Liverpool Royal Infirmary, England. The reading matter is exceptionally clear in imparting fine points of differential diagnosis as well as succinctly stating the logical points elicited in arriving at a definite diagnosis. To one beginning a surgical career such a book should be read twice each year.

EUGENE W. SKELTON

An Outline of Immunity.—By W. W. C. Topley, M.D. Octavo of 415 pages, illustrated. Baltimore, William Wood & Company, 1933. Cloth, \$6.00.

This is intended for the special student and investigator in this field. It is adequately practical throughout, emphasizing the applications of immunity to practice as well as demonstrating laboratory and field procedures. The general outline is excellent, and the use of sub-headings and spacing with different type forms adds greatly to emphasis and attractiveness. References included are basic and are not always those that agree with the author's conclusions. The reviewer is particularly complimentary in the selection of mathematical data and the illustrations in general.

IRVING M. DERRY

Acute Intestinal Obstruction.—By Monroe A. McIver, M.D. Octavo of 430 pages, illustrated. New York, Paul B. Hoeber, Inc., 1934. Cloth, \$7.50.

In this excellent comprehensive review of the subject, the author has divided his work into three parts. In Part 1, the author discusses the general picture of the disease; in Part 2, he deals with the diagnosis and methods of treatment; and in Part 3, there is a discussion of the experimental work which has been done to determine the cause of death from intestinal obstruction. The experimental work and the clinical and pathological material dealing with the subject are thoroughly discussed and a complete bibliography is appended at the end of each chapter.

The illustrations and the entire arrangement of the book are excellent. Both the surgeon and the internist as well as those interested in the experimental work relating to intestinal obstruction will derive a great deal of pleasure and value from this monograph.

IRVING GRAY

CARCINOMA OF THE TONSIL*Clinical Study of 176 Cases With Histologic Diagnoses*

JAMES J DUFFY MD

Assistant Attending Surgeon Memorial Hospital New York City

In the discussion of carcinoma of the tonsil, it is not often possible to isolate the tonsillar tumors from those of the pillars, because the disease has so far progressed when first seen that both these regions are involved, and usually one or more contiguous portions of the oral cavity

Because of the low incidence of tonsillar carcinoma in general, few clinical studies have been made, but the relative frequency of carcinoma of the tonsil in relation to the intra oral group of cancer should be a stimulus to greater efforts to make an early diagnosis, and especially to improve the therapy of this disease. The relative frequency is demonstrated by the fact that of every ten patients with intra oral cancer admitted to Memorial Hospital between 1919 and 1929, one had carcinoma of the tonsil

There is a large surface area of epithelium covering the tonsil, though limited to a small region. The lymphoid tissue of the tonsil is covered by the tunica mucosa, consisting of stratified epithelium of several layers, with flattened cells on the surface and columnar cells beneath. This epithelium serves as a lining to the microscopic depressions, between ten and twenty, which are the crypts. These are irregularly tubular and are sometimes branched. This epithelial surface with the many infoldings and with the convexity of the pillars, constitutes more epithelial surface than is apparent from casual inspection.

The diagnosis of carcinoma of the tonsil is not always simple. The first symptoms may be no more than would accompany a mild throat infection. The more common sequence of symptoms is discomfort as in ordinary infection of this region "sticking sensation" constant irritation, soreness,

especially on swallowing, and in advanced stages, pain, referable to ear, head, and neck. The local discomfort usually indicates that the lesion is not widespread, whereas if the reference of pain is to ear and head, the lesion will be found to be infiltrating the deeper tissues and the base of the tongue, or there is an obvious mass in the upper deep cervical regions, causing pressure on the cervical nerves.

The duration of symptoms in patients applying for admission is rarely less than two months, usually four months and often six or more months. A neoplasm of the tonsil may and usually does progress far in four months. Though the histologic grading, per se may not indicate a high grade of malignancy, the location of the growth, with its profuse blood supply and lymph drainage, causes a rapid growth of local lesion and early metastases.

A painless mass in the upper cervical region, or over the carotid bulb, may be a metastasis from an apparently insignificant cancer of the tonsil. This manifestation is often associated with the transitional cell or lymphoepithelioma type of tonsillar cancer. This type of metastasis is frequently incised under the diagnosis of "abscess," with only a casual examination of the oral cavity. When no pus is found, a tumor may be suspected, and then the patient is referred for further examination and diagnosis. Such a procedure tends to spread further metastases, allows fungation through the wound, and makes the treatment more difficult and less efficacious.

The clinical signs of tonsillar carcinoma are usually quite typical, but not routinely so. A microscopic study is sometimes necessary. The more usual type of lesion may be described as an ulcerated growth of varying size of tonsil or pillars, or both. The periphery of the ulcer is elevated, in-

durated, and irregular. The induration often extends into adjacent tongue, the soft palate, and occasionally on to the buccal mucosa, or floor of the mouth. The surface of the ulcer may be clean and granular, or the crater may be infected and sloughing. This appearance belongs to the more adult cell type of cancer; the transitional cell carcinoma and lymphepithelioma are nonulcerated in the early stage and may be overlooked unless a most careful search is made, even though there is in the cervical region a bulky growth of proved histology.

The differential diagnosis does not entail the consideration of many diseases of this region. The differentiated cell type might be simulated by lues or tuberculosis, though such confusion is unlikely. The radiosensitive, nonulcerating lesion may have the appearance of a hypertrophied tonsil, or more likely tonsillar lymphosarcoma. The consistence of the embryonal type of tonsillar carcinoma is not characteristic: the induration which is often considered typical of cancer is frequently lacking in transitional cell carcinoma and lymphepithelioma. The cervical metastases from a very small embryonal carcinoma may be similar to cervical Hodgkin's disease, though distribution of the adenopathy may be helpful (in Hodgkin's disease the adenopathy is usually general).

The region of the anterior tonsillar pillar is a possible site for an adenoid cystic carcinoma. This lesion often can be distinguished clinically by the absence of ulceration, and its consistence, which is that of encapsulated fluid under tension.

Other types of tonsillar tumors are so rare that they need not be considered in the differential diagnosis.

Tonsillar carcinoma is most frequent in the fifth and sixth decades, but it may occur at any age. The oldest patient was eighty-two and had a squamous carcinoma, Grade II. The youngest patient in this series was twenty-one. He had a transitional cell type carcinoma, Grade III, radiosensitive. There was bilateral cervical involvement. For nine months this patient had noted a swelling in his neck, and the mass had been incised and drained before admission to the hospital for treatment.

The surgical treatment of cancer of the tonsil has been most discouraging. Because of the poor results, there have been very few reports. Matthews (1912) did not have any three-year cures by tonsil-

lectomy and cautery, or by excision of growth by a lateral pharyngotomy. In 35 cases of lateral pharyngotomy collected by Matthews, there was a primary mortality of 13 per cent, another 30 per cent died within six months, and only 4 patients lived two years. There have been a few reports of single successfully operated cases, but these are of no value, unless it is known how many cases were treated.

In very few clinics are carcinomas of the tonsil subjected to surgery. When this is done, it is usually on the mistaken diagnoses of a benign lesion. Carcinoma of the tonsil is nearly everywhere—as is the case at Memorial Hospital—classified as a primarily surgically inoperable disease.

Since tonsillar carcinoma is not a surgical disease primarily, it cannot be divided into operable and inoperable groups. In this report those cases in which only two contiguous portions of this region are involved, as tonsillar and anterior pillar, are classified as early, unless there is widespread disease across the base of the tongue, for instance, in which case the disease is classified as advanced, as it is if three or more portions of the mouth are involved; as tonsil, anterior pillar, and soft palate, or anterior pillar, adjacent tongue, and floor of the mouth.

Of the 176 cases in this report, only 40 were classified as early, while in 136 cases the disease was advanced. In these 136 advanced cases are included 10 recurrent cases, in which tonsillectomy had been done elsewhere.

Several cases were included in the early group, even though cervical metastases were present, the reason therefor being to emphasize the fact that small primary lesions may give rise to metastases. If only those cases were considered early, in which the primary was limited to two contiguous regions, and at the same time showed no cervical involvement, there would be only 15 early cases, or 8.5 per cent.

In the histologic grading of the carcinomata of the tonsillar region, they were found to be as follows:

Grade I.....	8 per cent
Grade II.....	72 per cent
Grade III.....	5 per cent
Transitional and lymphepithelioma..	15 per cent

In 4 cases the section was too small to grade, and in one the characteristics were mixed transitional and squamous carcinoma, Grade II. Only one adenoid cystic epithelioma was found in the whole group

of 176 tonsillar neoplasms. This man, fifty-nine years old, failed to return after three years and two months, at which time he was free of disease.

Cervical metastases from carcinoma of the tonsil are frequent and usually early, especially in the transitional cell type and lymphepithelioma. The metastatic mass in the cervical region is often the manifestation of the disease which causes the patient to seek medical attention. Some of these masses have been incised under the diagnoses of abscess. This is most hazardous, because it may cause distant metastases, and permit fungation of the tumor through the incision wound.

In this group of 176 cases, 64 patients did not have cervical metastases when admitted to the hospital (36.4 per cent). New and Childrey, in 1931, reported 32.2 per cent of the tonsillar carcinoma patients had no palpable nodes on admission to the Mayo Clinic, but no mention was made of what proportions of the remainder were operable and inoperable. Of the 64 patients admitted to Memorial Hospital without palpable nodes, 18 developed cervical metastases (28 per cent), but 3 developed inoperable nodes, either too widespread unilaterally for operation, or on both sides of the neck. Forty-five cases had operable nodes on admission, and 67 patients had advanced inoperable metastases (25.6 and 38 per cent, respectively). The criteria on which these figures are based are those of any surgical clinic where operability depends on the technical possibility of surgery, rather than on the more rigid rules which are followed at Memorial Hospital. We add other criteria to the operable group, which places technically operable nodes in the inoperable class. This will be discussed under Treatment.

It is interesting to note the frequency of involvement of the opposite side of the neck and of both sides. Fourteen patients had nodes on both sides on admission; 5 having metastases on the same side as the lesion, promptly developed nodes on the opposite side, and 3 patients had cross metastases when first seen. The 17 patients with bilateral neck involvement, or cross metastases, which are practically the same, accounted for nearly 10 per cent of all cases admitted. If to these are added the 5 who developed metastases, then 12.5 per cent of the whole group had bilateral metastases. This shows the frequency of this type of metastases, which is exceeded

only by carcimoma of the soft palate, which is a mid oral lesion and might be expected to extend to both sides of the neck.

Besides the local metastases, carcinoma of the tonsil may metastasize to the mediastinum, lungs, liver, retroperitoneal glands, and to the bones. These more distant deposits are common to the more malignant types, especially the transitional cell carcinoma and lymphepithelioma.

The discussion of the treatment of carcinoma of the tonsil will be limited to the method used in this group, and thereby may serve for a comparison with the group now being treated by more vigorous external irradiation, in divided dosage, somewhat modified from the so-called Coutard technic. This consists of 300 or 350 r. of x-radiation to right and left neck, alternately on successive days, until a total dosage of 3,000 to 3,500 r. are delivered over each point in twenty days. The factors of this x-radiation are 200 K.V., 30 ma., 60 cm. T.S.D., $\frac{1}{2}$ cu., 2 al. filtration, and the size of the portal is usually 7.5 cm. Interstitial radiation is reserved for any residual disease.

The treatment of the cases here included may be simply outlined, omitting the more detailed description. On admission both sides of the neck were exposed to x-rays, or radium, or both, the beam of radiation being sufficiently large to include the primary lesion. The group of cases treated in the early days received mild erythema to each side of the neck; in the latter years, the dosage was higher, often producing desquamation. The exposure to radiation was given to each side on successive days. Then the primary growth was implanted with a varying amount of radon, depending on the size and its configuration. The patient was subsequently carefully observed, to note the regression of the primary lesion and the condition of the cervical region. Close observation of the primary is necessary to determine the course to be followed in the care of the neck. Neither surgery nor irradiation of the cervical region is indicated if the primary lesion cannot be controlled, and too frequently the primary neoplasms are uncontrollable. In this series 17 of those cases with no nodes on admission died of uncontrolled primary lesions, as did 7 patients with operable cervical metastases.

If the primary growth regressed satisfactorily, and no nodes were palpable in

the neck, special attention was directed to the detection of metastatic nodes. No surgery was done nor further radiation given unless indicated by the development of metastases. If operable nodes developed or were present on admission, a neck dissection was done when the primary lesion was healed or controlled. When a neck dissection was indicated, a complete dissection was done removing the jugular vein, sternomastoid muscle, and the contents of both anterior and posterior triangles of the neck. To be operable, it is not sufficient for the nodes to be technically resectable, but they must also be metastatic from an adult type of tumor, as shown by the biopsy of the primary growth. Metastases from transitional cell carcinoma and lymphepithelioma are never subjected to surgery. If external irradiation was inadequate to devitalize the cells, the mass was implanted with gold tubes of radon, either following surgical exposure or directly through the skin. This same procedure was followed in the technically inoperable group of more adult type of tumor, surgically exposing the less advanced lesions, and directly implanting radon seeds into those masses in which only mild palliation may be obtained. It must be understood that the previously described technic of treatment is applicable to this group of cases and is not the principle being followed at present which is based on delivery of greater amount of radiation by external means over a protracted period, utilizing interstitial for any residual disease.

It is not customary to report three-year cases of carcinoma, but since Berven, in his extensive study of tonsillar carcinoma, has reported three-year results, the same time interval will be used in this discussion.

Berven divided his cases into two groups: one comprising the 28 patients treated between 1919 and 1924, by what he calls the "old technic." This consisted of x-ray to each side of the neck with large portals, the fractionated dosage varying from $\frac{1}{3}$ to $\frac{1}{2}$ S.E.D. daily to alternate sides of the neck, to total about six to seven S.E.D. After this series of treatments, radium was applied to the surface of the primary tumor.

With this method of treatment no patient lived symptom-free for three years.

The second group of 18 cases, 1923 to 1927, was treated by the "new technic," consisting of radium irradiation at a longer

target skin distance, directed toward the primary lesion from four angles, namely, over tumor, from opposite side of head, from posterior portal, and finally over the face on the side of the tumor, a total of 80,000 mg. hr., the dosage varying over different portals. The amount of daily dosage was 6,000 mg. hr. The primary tumor was then treated by surface or by interstitial application of radium. In this group of 18 cases, 7 remained free of disease for three or more years, a percentage of 38.9.

This report comprises 176 cases between 1921 and 1930, inclusive. Of the 46 patients who had no cervical nodes throughout their course, 15, or 32.6 per cent, remained free of disease for three or more years. Others died of uncontrolled primary lesions, distant metastases, local infection, intercurrent disease, or were lost. Of the 18 cases who developed neck nodes after admission, 5 remained free of disease for three years or over, a percentage of 27.7.

The presence of operable metastatic nodes decreased the percentage to 15.5, only 7 out of 45 patients surviving free of disease for a period of three or more years. In the large group of 67 cases admitted with inoperable cervical nodes, only 5 survived the three year period clinically free of disease (7.5 per cent). The 3 patients lost after a period of observation of three years, though free of disease at the time, have not been included in the three-year tabulation of results. The reason for this is that most of the well patients have been free of disease for longer than three years, some for nine or ten years.

If the 176 cases are included in a composite tabulation, it is found that there are 32 patients clinically free of disease for three or more years (18.1 per cent).

This figure is unsatisfactory; nevertheless, it encourages us to persist in our efforts to improve the technic and results of radiation therapy in tonsillar carcinoma which is rarely, or never, suitable for surgery alone.

DISCUSSION

DR. DOUGLAS QUICK: The subject which Dr. Duffy has so ably presented ought to be of widespread interest. Peculiar and often insignificant lesions in and about the tonsillar fossa are frequently overlooked from the cancer standpoint. It is possible that the frequency of ulcerating inflammatory lesions on the surface of the tonsil may lead to this confusion on the part of the general practitioner or the nose and throat

specialist It is a fact, also, that relatively few tonsils are examined histologically after tonsillectomy

The doctor's percentage incidence of tonsillar fossa cancer seems to me rather high, yet it does indicate that growths in this area are not rare. Dr. Duffy's figures are taken from a department which has enjoyed a substantial popularity over a period of many years in an institution where certain of the major types of cancer are not cared for in such large numbers.

While the metastatic cervical nodes are frequently the first noticeable indication of real trouble, this evidence of late recognition is not as frequent with the tonsillar group as with those primary in the nasopharynx

Emphasis should be placed upon the fact that this group of tumors is strictly nonsurgical from the standpoint of extirpation Technical operability and real operability in cancer are two different things

Dr. Duffy's high percentage of histological Grade II cases should be of particular interest to the radiologist. They represent the group of cases that are on the borderline of controllability by intensive external irradiation The initial response to heavy modern external therapy is likely to be misleading If left to this alone, recurrence may be expected after a few months

in many instances. The majority of these cases are handled with greater safety by combined external and interstitial irradiation

I feel that the present wave of popularity of the so called "Coutard technique" is likely to leave, ultimately, many unnecessary failures in this group Dr. Duffy's percentage of strictly anaplastic growths (about 15 per cent) fits very closely with the clinical experience of the percentage of these cases controllable by external therapy

PREVENTIVE MEDICINE PAYS

It pays in cold cash This is the discovery of a committee of the Michigan State Medical Society that has been looking into the monetary side of preventive medicine The committee says plainly that a satisfactory way to enhance the monetary return to the physician is to increase his services in the preventive field When in good health the patient is more inclined and better able to pay for medical services

The truth of this statement is borne out by experience in Detroit, where during the past three years, due to the reduction in the diphtheria death rate, it is estimated that the physicians of the community have lost \$60,000 This figure is based upon an assumed cost of \$35 for each case of diphtheria treated This loss would have accrued to the medical profession irrespective of whether free clinics were employed as a means

of immunizing children of susceptible age or whether a program of medical participation had been adopted Under the latter plan, however, the physicians have received, either through payment direct by the parent or through an honorarium provided by the Health Department, more than \$300,000

In other words, medical service has paid this group of 1,100 cooperating physicians five times as much as they have lost in curative medicine. This demonstrates very distinctly that to the physicians preventive medicine is more profitable than curative medicine.

At the same time the public has gained The average cost of a case of diphtheria is \$35, the average cost of preventive but \$3 Again the advantage in favor of preventive medicine is more than ten to one.

\$3 TO REPAIR A BROKEN HEAD

A double interest attaches to the following item It is an English surgeon's bill of 1689, showing that his charge for repairing a broken head was 10 shillings or \$2 50, for medicaments, and 2 shillings, or 50 cents, for his own services The second interesting point is that it was found in a London paper by Dr. James Vander Veer, who sent it to Dr. J. S. Lawrence, Executive Officer of our Legislative Bureau, who sent it to Dr. Peter Irving, of the Journal Management Committee It is this sort of reader interest and cooperation that will make any magazine like our JOURNAL truly successful The good surgeon's bill runs as follows Septemb. ye 22, 1689 T. Edgshaw a Coachman sore wounded on the head, the Cranium bare, the breadth of Crown peace fell into my hand—Charges Melrosarium two shillings and sixpence, Spirit of

Wine three shillings, Brandy one shilling; Plaster one shilling and sixpence, tove (tow?) to dress sixpence, fomentation two shillings, for own paines nothing, for my servants two shillings total twelve shillings and sixpence Received the Some in this Bill by mee Thos Wotton.

A whimsical writer in the *London Punch* observes that psycho analysis which is easier to understand than to spell tells us what we really think when we think we think a thing Without psycho-analysis we should never know that when we think a thing the thing we think is not the thing we think we think, but only the thing that makes us think we think the thing we think we think.

SPUTUM EXAMINATIONS AND THE PRACTICING PHYSICIAN

ROBERT E. PLUNKETT, M.D., and N. STANLEY LINCOLN, M.D.

From the Division of Tuberculosis, State Department of Health, Albany

Etiologically, diagnostically, prognostically, and epidemiologically, the tubercle bacillus is the one important factor around which all branches of phthisiology revolve. Nevertheless, it is astounding that of 65,335 reports of pulmonary tuberculosis received by the New York State Department of Health in the past nine years, less than one-half (about 45 per cent) of the cards showed that the patient had had a sputum examination.¹ Even though 75 per cent were in the advanced stage at the time of reporting, only 34 per cent were reported as having a positive sputum. Obviously, this does not truly represent the facts. If from the total reports is subtracted the group received from physicians associated with tuberculosis hospitals (about 47 per cent of the total), both the relative number and percentage of patients having had the sputum examined, as reported by the local physicians, become increasingly small. Whatever the explanation of this situation may be, immediate correction is essential for the common good.

Even though the death and morbidity rates for tuberculosis have been declining steadily for several years, the percentage of cases reported as the pulmonary form has shown a slight increase. In other words, there has been a more rapid actual and relative decrease in the number of extrapulmonary tuberculosis. The significance of this observation is that the sputum has become the most important vehicle for the transmission of the tubercle bacillus. Any intelligent program of tuberculosis control from the point of view of the patient, the physician and the community, must be based upon an accurate knowledge of the bacillary content of the sputum. This knowledge can only come by adequate sputum examination in a well-equipped and staffed laboratory. Official public health agencies consider the laboratory of such vital importance as an adjunct in the control of communicable disease, that the expenses of some laboratories in New York State are paid either in part or wholly from public funds. The cost to the individual practitioner of examination by these laboratories is nothing, except the postage for the specimen submitted and the time to fill out a form for the guidance of

his technical coworker. The steadily increasing number, delicacy, and reliability of examinations offered, justifies this confidence.

In the application of the fundamental principles of communicable disease control to tuberculosis, the significance of sputum and its examination deserves first consideration. If a patient has an amount of sputum greater than the normal secretions, it is *prima facie* evidence that there is a morbid process somewhere in the respiratory or upper respiratory tract including the mouth. If the lesion be hidden from direct view, particularly if it be intrapulmonary, the examination of sputum may tell the examiner the etiological factor, and not infrequently the evolution of the lesion. One may inquire why it is essential to examine sputum for tubercle bacilli, when there are present no etiologic symptoms or signs and sputum has been present for a short period. "The answers are that clinical experience shows that some of these cases of recently manifested and apparently trivial disorders are really cases of tuberculosis of the lungs which are in such an early manifestational state, that no symptoms, especially suggestive of tuberculosis of the lungs exist. . . ." (Shaw²). From a point of view of diagnosis, the demonstration of tubercle bacilli in the sputum is the only method of unequivocal value. All other tests or examinations belong in the field of presumptive evidence.

There is an attitude among practitioners and some laboratory workers that it is a greater tragedy to make a wrong positive diagnosis of pulmonary tuberculosis than to miss the diagnosis when tuberculosis is actually present. This attitude should be challenged. If a person is incorrectly diagnosed tuberculous, the injustice is minor, for the reason that only an incorrect name has been applied to a morbid process, the diagnosis can be readily corrected and the error is never a cause of death. On the other hand, if a diagnosis is not made in the presence of active disease, the patient not only may be robbed of his opportunity for successful treatment, but also in ignorance is transmitting to his contacts and family the seeds of disease which, in turn, may lead to a tragic end.

From the point of view of guide for therapy, the physician must know whether the sputum contains tubercle bacilli constantly or intermittently, and in gross or occasional numbers. It is common clinical experience that patients with a persistently positive sputum over a prolonged period do poorly. One of the aims of present-day treatment, especially those forms based on the principle of collapse of the lung, is to render the sputum bacilli-free and the patient sputum-free.

From the point of view of public health, we know that the tuberculous individual may be either a definite clinical case or he may be without symptoms and yet have bacilli-laden sputum. In a practical sense, this latter individual is a "carrier" and is difficult to control because of his apparent wellbeing. Even though a person is the source of infection, the sputum is the vehicle of dissemination and control must be aimed at the proper disposal and control of this vehicle. "By removing the source, the infection rate diminishes and the disease tends to disappear."³

In other words, one of the most important steps in the diagnosis of the presenting case, in determining the proper course of treatment in the diagnosed case, and in the solution of the tuberculosis problem in any community, is adequate sputum examination.

Of what does an adequate sputum examination consist? It consist of the following steps:

1. Adequate samples correctly collected in appropriate receptacles.

2. Examination by direct smear of carefully selected portions of specimens collected on several consecutive days. If these are negative, or especially, if the amount of sputum is small, a three-day specimen should be collected and examined by smear. If, in turn, this is negative, then

3. Concentration of either single or three-day specimens by any of the accepted methods and study of the sediment by: (a) Direct smear; (b) Culture on artificial media; and/or (c) Inoculation into a laboratory animal, preferably the guinea pig.

The need for the submission of an adequate number of specimens cannot be overstressed. Cultural and animal studies are time consuming and expensive, but this consideration should not deter the physicians in their use when properly indicated.

In order to obtain the maximum information, the specimen must be endowed with those characteristics which are translatable by technical methods to useful data. More likely than not, the patient is totally ignorant of medical terms even to the point that he may not realize that he has

"sputum" or "expectoration." In fact, the less the store of a patient's knowledge, the more necessary it becomes to explain in detail what is desired. Saliva, nasal and nasopharyngeal secretions, and foreign material of no medical interest, only serve to complicate the problem of the technical observer. Only that material which is coughed up "from the lungs" or "bronchial tubes" is useful for examination. If necessary, in order to obtain an adequate amount, such material may be collected for a period of one to three days.

A receptacle for the collection of sputum specimens is usually of glass, of one-ounce capacity, and so designed that it is easy to expectorate into without soiling the exterior. These should be furnished by the laboratory. Perhaps it is not sufficiently recognized that acid-fast bacilli of the air, dust, hay and straw, butter, and those found in the average cold-water tap are not pathogenic for man but may lead to false report if not guarded against by appropriate methods. Moreover, certain fats and oils should not come in contact with the receptacle because they may render nonacid-fast bacteria definitely acid-fast. These and other common sources of error and their prevention are common knowledge to well-trained technical workers and in well-run laboratories.⁴

The method of examination of an untreated specimen of sputum by direct smear has a large percentage of error even when the maximum skill is used. The tubercle bacilli occur in unevenly distributed clumps and their inclusion in the droplet examined (estimated at 1/100 c.c.) is a matter of chance.³ Whether we accept Corper's estimate of 100,000 bacilli per cubic centimeter or Woolley's estimate of 5,000 per cubic centimeter necessary for consistent positive smears, it is obvious that many specimens of sputum may be repeatedly negative by this method and still contain significant numbers of tubercle bacilli, particularly when it has been demonstrated that 10 to 100 bacilli may produce progressive disease in guinea pigs in two months.^{5, 6, 7} A sputum cannot be considered negative for tubercle bacilli, therefore, until it has been studied by more accurate methods.

The next step is the "concentration" or "enrichment" of the sputum specimen. The object of this procedure is to render the soluble portions of the sputum readily fluid so that the insoluble portion (of which tubercle bacilli are a part) may be gathered into a small volume which is more easily and effectively searched. It is at this

point that the value of proper collecting of specimens shows greatest technical results.

This method was first developed by Biedert,⁸ in 1886, when he boiled the sputum with sodium hydroxide. Uhlenhuth,⁹ in 1908, developed the well-known antiformin method of concentration. Petroff,¹⁰ in 1915, used dilute sodium hydroxide and Löwenstein¹¹ and Sumiyoshi,¹² in 1924, used dilute sulphuric acid. Each of the last three methods have their proponents, but the last two appear to be most useful when the sediment is to be cultured on artificial media or inoculated into the laboratory animal. The reason seems to be that they are the most efficient in killing contaminating organisms so plentiful in sputum and at the same time doing the least damage to the viability of the tubercle bacilli. The development of the concentration idea has been one of the most significant advances in the examination of the sputum in the past twenty-five years.

If, upon microscopic examination of the sediment of a concentrated specimen, bacilli are found which are morphologically identical with tubercle bacilli, this observation should be confirmed by repeated examination of an additional specimen or specimens, or by bacteriological culture, and/or animal inoculation. No definite diagnosis, either positive or negative for tuberculosis, should ever be made when the morphology of the acid-fast organisms seen are not typical of tubercle bacilli. If the forms are atypical, further study is not only indicated but highly essential.

The artificial media to be preferred is that which gives the best results in the hands of the technical coworker. The number of media in current use is legion and the literature fails to reveal that any one has a definite universal superiority. Culture methods have demonstrated tubercle bacilli in as high as 71 per cent of sputum from a series of 100 patients, which had previously been negative by direct smear for a period of four months to two years.¹³ If typical colonies appear from which smears show acid-fast rods

morphologically identical with the tubercle bacillus, then a diagnosis of positive is amply justified.

The most reliable method for the demonstration of the tubercle bacilli is freely admitted to be animal inoculation. Therefore, this method is to be preferred, especially where other tests do not yield definite results and whenever it is desirable to know the relative virulence and the type of the organism concerned.

A comparison of the cultural and animal inoculation methods for the isolation and identification of the tubercle bacilli is most interesting and instructive. In order to obtain a "certified" diagnosis of tuberculosis one must follow through the three postulates of Koch which involves the use of both methods.⁵ In practice, Sweany and Stradnichenko¹⁴ found that practically every patient remains positive by culture and animal inoculation a few months longer than by the direct examination and that a few patients are found who were always negative by the microscopic examination of the concentrate. The culture method is cheaper, quicker and is not subject to the vicissitudes of laboratory animals. However, the laboratory animal, especially the guinea-pig, is not susceptible to the contaminants usually found in sputum, gives an idea of virulence of the organism, and, in general, still remains the court of last appeal in the isolation and identification of the bacillus tuberculosis.

ANNOUNCEMENT

The Radiological Society of North America will hold its next Annual Meeting at the Hotel Peabody, Memphis, Tennessee, December 3-7, 1934. The Medical Profession is cordially invited to attend. Further information may be obtained by addressing the Secretary-Treasurer, Dr.

Donald S. Childs, 607 Medical Arts Building, Syracuse, New York.

DR. A. L. L. BELL, BROOKLYN, N. Y.

DR. R. C. HALL, UTICA, N. Y.

Counsellors.

A STUDY OF 1,250 BASAL METABOLISMS DURING PREGNANCY

Clinical Presentation of Cases

EDWARD C. HUGHES, M.D.

Syracuse

One of the most interesting studies in obstetrics to-day is that of the glands of internal secretion. These structures present vast material for speculation. It is considered that the pituitary, thyroid, pancreas, adrenals and ovaries are more closely related to pregnancy and the sexual life of woman. It has been thought that these glands may cause changes in the metabolism of the body at that time.

It is the purpose of this article to present a study of 1,250 basal metabolisms done during pregnancy. No claim is made of any striking discoveries, or of conclusive inferences that may be drawn, because the series is small. However, it is felt that the study will bring out some interesting data, and may help to clear up some of the questions about metabolism during those months.

This study began four years ago and consists entirely of private patients. Because the metabolic machine is rather a crude instrument and because the chances of error are considerable, every effort was made to approach basal conditions as nearly as possible. The tests were done by a well-trained technician, the patients were well-informed about the tests, and the element of apprehension reduced to a minimum.

The first problem was to attempt to establish a normal of metabolic readings throughout pregnancy. This was difficult because of the numerous factors constantly influencing the individual. The change in the endocrine function, the growth of the fetus, and many other things had to be taken into consideration. The most important of these things were the increasing weight, the diet, the exercise, the age, the height, and the atmospheric changes. No doubt, also, sectional changes in various parts of the country may alter the normal metabolism. All of these patients were on a high carbohydrate diet in the first trimester, balanced diet in the second trimester, and a low fat and moderately low protein diet in the last trimester. The exercise was limited in the first three months to housework, and in the second

trimester the patient was encouraged to walk two miles a day.

The first manner of establishing a normal was as follows: The average conditions which prevailed during all these tests were taken as a basis, and therefore a synthetic woman was metabolized each month of pregnancy under average conditions, and a curve plotted. The second way was to aggregate in each month all the tests done, and the mean of these was taken as a normal. The third way was to accept the standard already established for everyone, and to choose plus 10 and minus 10 as normal limits.

It was found that 56 per cent of these patients were within these normal limits in the first trimester, 71 per cent in the second trimester, and 75 per cent in the last trimester. In analyzing the curve it can be seen that there is a slight increase at the sixth week of pregnancy; a lowering in the second, third and fourth months, the lowest being in the third month; and then a gradual increase until it reaches a plus in the last trimester. Also, it is noticeable that 77 per cent of these women showed a rate below zero in the second, third, and fourth months; 68 per cent in the fifth month; 60 per cent in the sixth month; 39 per cent in the seventh month; 26 per cent in the eighth month; and 17 per cent in the ninth month. This is somewhat contrary to the literature, most of which states a plus rate throughout the entire pregnancy. This is represented graphically in Plate I.

The lowering of the rate found in the third and fourth months particularly has also been mentioned by Rowe and associates of Boothby at the Mayo Clinic. After reviewing this curve it appears that in the majority of cases, pregnancy has no great effect upon the general metabolism except to cause these changes. However, there is a definite percentage of cases that have shown marked changes, and it is this group of women that have most engaged our interest.

In order to bring out more of the clinical side, an attempt has been made to find

out if any of the symptoms and signs associated with various stages of pregnancy are in any manner related to the change of metabolic rate from normal. Patients presenting these irregularities constituted 44 per cent of those examined in the first trimester, 29 per cent in the second trimester, and 25 per cent in the third trimester. These peculiarities were unusually high or low rates, those having a sudden lowering of fifteen or more degrees, and those who failed to increase with pregnancy.

Plate I

Case 150	Below -10	+10	Above +10	Decrease of 15 Points	Rate
Loss of Wt	53%	33%	22%	90%	
Anorexia	85%	45%	5%	92%	
Drop in BP					
Mod Nausea	81%	35%	5%	94%	
Severe Nausea	41%	83%	0	50%	
Mod Vomiting	81%	18%	5%	94%	
Severe Vomiting	19%	83%	0	44%	
Constipation	74%	28%	22%		
Exhaustion	80%	51%	32%		

Plate II

During pregnancy, which has been divided into three parts—first, second, and third trimesters—certain conditions stand out as characteristic of each. The period that presents the most complaints is the first trimester. This period may be thought of as the destructive period, the patient rarely showing stimulation at this time. The most frequent signs and symptoms are extreme exhaustion, sleepiness, nausea and vomiting, constipation, anorexia, loss of weight, and general slowing of the entire system. During this period, 165 patients were studied and metabolized. These cases have been divided into four groups, those above plus 10, those between

plus 10 and minus 10, and those below minus 10. The women showing a sudden drop in metabolic rate of 15 or more points constituted the fourth group. These changes took place regardless of the previous level of metabolism.

Plate II presents percentages in 150 patients who exhibited these symptoms.

It appears then that patients with a rate below the minus 10 level, patients developing a decrease in rate whether it be in the first or second trimesters, present the most difficulty.

Plate III

The optimum patient then would be as represented in the three graphs in Plate III.

(1) Mrs. T., age 28, came to the office before pregnancy for an examination, at which time her metabolic rate was plus 4. Two months later she returned pregnant and her rate had increased to plus 6. There was then a slight lowering, followed by a gradual increase until she reached a plus 14. She had no complaints and there was no change in the blood pressure, 110/80.

(2) Mrs. H., age 23, first baby died in utero from twisted umbilical cord. Rate two months before pregnancy, minus 5. There was a definite increase in rate from the beginning and no symptoms developed. Blood pressure was 120/80.

(3) Mrs. Z., age 27. Rate before pregnancy was minus 17. At two months pregnant, the rate remained stationary. She felt well except for malaise, loss of 8 lb. weight in the first trimester, and blood pressure of 90/70 at that time. After the fourth month, stimulation took place followed by increase in rate and general improvement.

The less favorable cases are those showing a drop in rate, and are illustrated by the following two cases, Graph I and II in Plate IV.

(1) Mrs. R., age 33, sterile seven years. After lipiodol injection of the uterus, patient menstruated once and then became pregnant. Before pregnancy, basal metabolism was plus 13. At the sixth week there was quite an increase, and with this increase the patient was irritable, nerv-

ous, had mild tremor, and increase in pulse rate. The second month the basal metabolism began to drop, first to plus 8 and then to minus 3. With this change, symptoms began to develop and nausea and vomiting were continuous and severe. Blood pressure dropped from 130 to 100, there was a 6 lb. loss of weight, and the patient became extremely sleepy. From the fourth and fifth months to the eighth month there was a slow increase in basal metabolism, blood pressure and weight, and the signs and symptoms abated.

(2) Mrs. O., age 32, showed a basal metabolism of minus 2 before pregnancy. She felt well until the second month when nausea and vomiting became very severe, lasting all day and night. There was a lowering of rate until the third month when it was minus 10 and the symptoms were much worse. The constipation was marked

lack of it, but probably to general glandular changes.

Many statements have appeared claiming that patients with hypothyroidism are prone to miscarriage, this diagnosis being made on the low rate entirely. Thirteen patients having miscarriage were tested. Ten patients had minus rates ranging from minus 25 to minus 1. Three patients had rates from plus 6 to plus 12. It was noted that in two patients with rates of minus 25 and minus 15, respectively, the ovum had failed to acquire growth of more than six to eight weeks although both were thought

Plate IV

and quite a problem. In the fourth month she was given thyroid extract. There was an improvement, which may or may not have been due to the extract.

The least favorable of all cases is the patient beginning with an unusually low rate and dropping lower, represented by Graph III in Plate IV.

(3) Mrs. M., age 26, sterile three years, irregular periods, malaise and constipation. One year prior to pregnancy, metabolism was minus 21. Upon treatment, rate increased only to decrease some months later. When next seen, she was three months pregnant. She had lost 22 lb. weight in the three months, was dehydrated, weak, exhausted, continually nauseated and vomiting, almost obstipation, and blood pressure was 80/70. Her rate had dropped to minus 41. She was given sugar solution, high carbohydrate diet and thyroid for the remainder of her pregnancy, and after several weeks improvement began.
